This file consists of the following major classes:

Element classes:

- *Tableau*
- *SemistandardTableau*
- *StandardTableau*
- *RowStandardTableau*
- *IncreasingTableau*

Factory classes:

- *Tableaux*
- *SemistandardTableaux*
- *StandardTableaux*
- *RowStandardTableaux*
- *IncreasingTableaux*

Parent classes:

- *Tableaux_all*
- *Tableaux_size*
- *SemistandardTableaux_all* (facade class)
- *SemistandardTableaux_size*
- *SemistandardTableaux_size_inf*
- *SemistandardTableaux_size_weight*
- *SemistandardTableaux_shape*
- *SemistandardTableaux_shape_inf*
- *SemistandardTableaux_shape_weight*
- *StandardTableaux_all* (facade class)
- *StandardTableaux_size*
- *StandardTableaux_shape*
- *IncreasingTableaux_all* (facade class)
- *IncreasingTableaux_size*
- *IncreasingTableaux_size_inf*
- *IncreasingTableaux_size_weight*
- *IncreasingTableaux_shape*
- *IncreasingTableaux_shape_inf*
- *IncreasingTableaux_shape_weight*
- *RowStandardTableaux_all* (facade class)
- *RowStandardTableaux_size*
- *RowStandardTableaux_shape*

For display options, see *Tableaux.options()*.

Todo:

- Move methods that only apply to semistandard tableaux from tableau to semistandard tableau
- Copy/move functionality to skew tableaux
- Add a class for tableaux of a given shape (eg Tableaux_shape)

---

class sage.combinat.tableau.**IncreasingTableau**(*parent*, *t*, *check=True*)

Bases: *Tableau*

A class to model an increasing tableau.

INPUT:

- `t` – a tableau, a list of iterables, or an empty list

An *increasing tableau* is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns.

EXAMPLES:

```
sage: t = IncreasingTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = IncreasingTableau(t); s
[[1, 2], [2]]
sage: IncreasingTableau([]) # The empty tableau
[]
```

You can also construct an *IncreasingTableau* from the appropriate `Parent` object:

```
sage: IT = IncreasingTableaux()
sage: IT([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- *Tableaux*
- *Tableau*
- *SemistandardTableaux*
- *SemistandardTableau*
- *StandardTableaux*
- *StandardTableau*
- *IncreasingTableaux*

K_bender_knuth(*i*)

Return the `i`-th K-Bender-Knuth operator (as defined in [DPS2017]) applied to `self`.

The i-th K-Bender-Knuth operator swaps the letters i and $i+1$ everywhere where doing so would not break increasingness.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_bender_knuth(2)
[[1, 2, 4], [3, 4, 5]]
sage: T.K_bender_knuth(3)
[[1, 3, 4], [2, 4, 5]]
```

K_evacuation(*ceiling=None*)

Return the K-evacuation involution from [TY2009] to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

K_promotion(*ceiling=None*)

Return the K-promotion operator from [Pec2014] applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_promotion()
[[1, 2, 3], [3, 4, 5]]
sage: T.K_promotion(6)
[[1, 2, 3], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_promotion()
[[2, 3, 4], [3, 4, 5], [4]]
```

K_promotion_inverse(*ceiling=None*)

Return the inverse of K-promotion operator applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_promotion_inverse()
[[1, 2, 4], [3, 4, 5]]
sage: T.K_promotion_inverse(6)
[[2, 4, 5], [3, 5, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_promotion_inverse()
[[1, 2, 4], [2, 4, 5], [4]]
```

check()

Check that `self` is a valid increasing tableau.

descent_set()

Compute the descents of the increasing tableau `self` as defined in [DPS2017].

The number i is a *descent* of an increasing tableau if some instance of $i+1$ appears in a lower row than some instance of i.

Note: This notion is close to the notion of descent for a standard tableau but is unrelated to the notion for semistandard tableaux.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,2,4],[3,5,6]])
sage: T.descent_set()
[2, 4]
sage: U = IncreasingTableau([[1,3,4],[2,4,5]])
sage: U.descent_set()
[1, 3, 4]
sage: V = IncreasingTableau([[1,3,4],[3,4,5],[4,5]])
sage: V.descent_set()
[3, 4]
```

dual_K_evacuation(*ceiling=None*)

Return the dual K-evacuation involution applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.dual_K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.dual_K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.dual_K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

class sage.combinat.tableau.**IncreasingTableaux**(***kwds*)

Bases: *Tableaux*

A factory class for the various classes of increasing tableaux.

An *increasing tableau* is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

INPUT:

Keyword arguments:

- `size` – the size of the tableaux
- `shape` – the shape of the tableaux
- `eval` – the weight (also called binary content) of the tableaux, where values can be either 0 or 1 with position i being 1 if and only if i can appear in the tableaux
- `max_entry` – positive integer or infinity (`oo`); the maximum entry for the tableaux; if `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`

Positional arguments:

- the first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition
- the second keyword argument will always be interpreted as `eval`

Warning: The `eval` is not the usual notion of `eval` or `weight`, where the i-th entry counts how many i's appear in the tableau.

EXAMPLES:

```
sage: IT = IncreasingTableaux([2,1]); IT
Increasing tableaux of shape [2, 1] and maximum entry 3
sage: IT.list()
[[[1, 3], [2]], [[1, 2], [3]], [[1, 2], [2]], [[1, 3], [3]], [[2, 3], [3]]]

sage: IT = IncreasingTableaux(3); IT
Increasing tableaux of size 3 and maximum entry 3
sage: IT.list()
[[[1, 2, 3]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 2], [2]],
 [[1, 3], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

sage: IT = IncreasingTableaux(3, max_entry=2); IT
Increasing tableaux of size 3 and maximum entry 2
sage: IT.list()
[[[1, 2], [2]]]

sage: IT = IncreasingTableaux(3, max_entry=4); IT
Increasing tableaux of size 3 and maximum entry 4
sage: IT.list()
[[[1, 2, 3]],
 [[1, 2, 4]],
 [[1, 3, 4]],
 [[2, 3, 4]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 4], [2]],
 [[1, 2], [4]],
 [[1, 2], [2]],
 [[1, 4], [3]],
 [[1, 3], [4]],
 [[1, 3], [3]],
 [[1, 4], [4]],
 [[2, 4], [3]],
 [[2, 3], [4]],
 [[2, 3], [3]],
 [[2, 4], [4]],
 [[3, 4], [4]],
 [[1], [2], [3]],
 [[1], [2], [4]],
 [[1], [3], [4]],
 [[2], [3], [4]]]
```

(continues on next page)

(continued from previous page)

```
sage: IT = IncreasingTableaux(3, max_entry=oo); IT
Increasing tableaux of size 3
sage: IT[123]
[[5, 7], [6]]

sage: IT = IncreasingTableaux(max_entry=2)
sage: list(IT)
[[], [[1]], [[2]], [[1, 2]], [[1], [2]]]
sage: IT[4]
[[1], [2]]

sage: IncreasingTableaux()[0]
[]
```

See also:

 [[1, 2]],
 [[1, 3]],
 [[2, 3]],
 [[1], [2]],
 [[1], [3]],
 [[2], [3]],
 [[1, 2, 3]],
 [[1, 3], [2]],
 [[1, 2], [3]],
```

(continues on next page)

(continued from previous page)

```
 [[1, 2], [2]],
 [[1, 3], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]
```

class sage.combinat.tableau.**IncreasingTableaux_shape**(*p*, *max_entry=None*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed shape p with a given max entry.

An increasing tableau with max entry i is required to have all its entries less or equal to i. It is not required to actually contain an entry i.

INPUT:

- `p` – a partition
- `max_entry` – the max entry; defaults to the size of `p`

class sage.combinat.tableau.**IncreasingTableaux_shape_inf**(*p*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed shape p and no maximum entry.

class sage.combinat.tableau.**IncreasingTableaux_shape_weight**(*p*, *wt*)

Bases: *IncreasingTableaux_shape*

Increasing tableaux of fixed shape p and binary weight wt.

class sage.combinat.tableau.**IncreasingTableaux_size**(*n*, *max_entry=None*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed size n.

class sage.combinat.tableau.**IncreasingTableaux_size_inf**(*n*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed size n with no maximum entry.

class sage.combinat.tableau.**IncreasingTableaux_size_weight**(*n*, *wt*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed size n and weight wt.

class sage.combinat.tableau.**RowStandardTableau**(*parent*, *t*, *check=True*)

Bases: *Tableau*

A class to model a row standard tableau.

A row standard tableau is a tableau whose entries are positive integers from 1 to m that increase along rows.

INPUT:

- `t` – a Tableau, a list of iterables, or an empty list

EXAMPLES:

```
sage: t = RowStandardTableau([[3,4,5],[1,2]]); t
[[3, 4, 5], [1, 2]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
```

(continues on next page)

(continued from previous page)

```
3  4  5
1  2
sage: t.is_standard()
False
sage: RowStandardTableau([]) # The empty tableau
[]
sage: RowStandardTableau([[3,4,5],[1,2]]) in StandardTableaux()
False
sage: RowStandardTableau([[1,2,5],[3,4]]) in StandardTableaux()
True
```

When using code that will generate a lot of tableaux, it is more efficient to construct a *RowStandardTableau* from the appropriate Parent object:

```
sage: ST = RowStandardTableaux()
sage: ST([[3, 4, 5], [1, 2]])
[[3, 4, 5], [1, 2]]
```

See also:

- *Tableau*
- *StandardTableau*
- *SemistandardTableau*
- *Tableaux*
- *StandardTableaux*
- *RowStandardTableaux*
- *SemistandardTableaux*

check()

Check that self is a valid row standard tableau.

class sage.combinat.tableau.**RowStandardTableaux**

Bases: *Tableaux*

A factory for the various classes of row standard tableaux.

INPUT:

- either a non-negative integer (possibly specified with the keyword n) or a partition

OUTPUT:

- with no argument, the class of all standard tableaux
- with a non-negative integer argument, n, the class of all standard tableaux of size n
- with a partition argument, the class of all standard tableaux of that shape

A row standard tableau is a tableau that contains each of the entries from 1 to n exactly once and is increasing along rows.

All classes of row standard tableaux are iterable.

EXAMPLES:

```
sage: ST = RowStandardTableaux(3); ST
Row standard tableaux of size 3
sage: ST.first()                                                    #␣
↪needs sage.graphs
[[1, 2, 3]]
sage: ST.last()                                                     #␣
↪needs sage.graphs sage.modules
[[3], [1], [2]]
sage: ST.cardinality()                                              #␣
↪needs sage.graphs sage.modules
10
sage: ST.list()                                                     #␣
↪needs sage.graphs sage.modules
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

See also:

- *Tableaux*
- *Tableau*
- *SemistandardTableaux*
- *SemistandardTableau*
- *RowStandardTableau*
- *StandardSkewTableaux*

Element

alias of *RowStandardTableau*

class sage.combinat.tableau.**RowStandardTableaux_all**

Bases: *RowStandardTableaux*, DisjointUnionEnumeratedSets

All row standard tableaux.

class sage.combinat.tableau.**RowStandardTableaux_shape**(*p*)

Bases: *RowStandardTableaux*

Row Standard tableaux of a fixed shape p.

cardinality()

Return the number of row standard tableaux of this shape.

This is just the index of the corresponding Young subgroup in the full symmetric group.

EXAMPLES:

```
sage: RowStandardTableaux([3,2,1]).cardinality()
60
sage: RowStandardTableaux([2,2]).cardinality()
6
sage: RowStandardTableaux([5]).cardinality()
1
sage: RowStandardTableaux([6,5,5,3]).cardinality()
1955457504
sage: RowStandardTableaux([]).cardinality()
1
```

class sage.combinat.tableau.**RowStandardTableaux_size**(*n*)

Bases: *RowStandardTableaux*, DisjointUnionEnumeratedSets

Row standard tableaux of fixed size n.

EXAMPLES:

```
sage: [t for t in RowStandardTableaux(1)]                                   #␣
↪needs sage.graphs
[[[1]]]
sage: [t for t in RowStandardTableaux(2)]                                   #␣
↪needs sage.graphs
[[[1, 2]], [[2], [1]], [[1], [2]]]
sage: list(RowStandardTableaux(3))                                          #␣
↪needs sage.graphs
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableaux(4).an_element()
[[1, 2, 3, 4]]
```

class sage.combinat.tableau.**SemistandardTableau**(*parent*, *t*, *check=True*)

Bases: *Tableau*

A class to model a semistandard tableau.

INPUT:

- `t` – a tableau, a list of iterables, or an empty list

OUTPUT:

- A SemistandardTableau object constructed from `t`.

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns.

EXAMPLES:

```
sage: t = SemistandardTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = SemistandardTableau(t); s
[[1, 2], [2]]
sage: SemistandardTableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a SemistandardTableau from the appropriate `Parent` object:

```
sage: SST = SemistandardTableaux()
sage: SST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- *Tableaux*
- *Tableau*
- *SemistandardTableaux*
- *StandardTableaux*
- *StandardTableau*

check()

Check that `self` is a valid semistandard tableau.

class sage.combinat.tableau.**SemistandardTableaux**(***kwds*)

Bases: *Tableaux*

A factory class for the various classes of semistandard tableaux.

INPUT:

Keyword arguments:

- `size` – The size of the tableaux
- `shape` – The shape of the tableaux
- `eval` – The weight (also called content or evaluation) of the tableaux
- `max_entry` – A maximum entry for the tableaux. This can be a positive integer or infinity (`oo`). If `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`.

Positional arguments:

- The first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition
- The second keyword argument will always be interpreted as `eval`

OUTPUT:

- The appropriate class, after checking basic consistency tests. (For example, specifying `eval` implies a value for max_entry).

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

Classes of semistandard tableaux can be iterated over if and only if there is some restriction.

EXAMPLES:

```
sage: SST = SemistandardTableaux([2,1]); SST
Semistandard tableaux of shape [2, 1] and maximum entry 3
sage: SST.list()                                                              #␣
↪needs sage.modules
[[[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]]]

sage: SST = SemistandardTableaux(3); SST
Semistandard tableaux of size 3 and maximum entry 3
sage: SST.list()                                                              #␣
↪needs sage.modules
[[[1, 1, 1]],
 [[1, 1, 2]],
 [[1, 1, 3]],
 [[1, 2, 2]],
 [[1, 2, 3]],
 [[1, 3, 3]],
 [[2, 2, 2]],
 [[2, 2, 3]],
 [[2, 3, 3]],
 [[3, 3, 3]],
 [[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

sage: SST = SemistandardTableaux(3, max_entry=2); SST
Semistandard tableaux of size 3 and maximum entry 2
sage: SST.list()                                                              #␣
↪needs sage.modules
[[[1, 1, 1]],
 [[1, 1, 2]],
 [[1, 2, 2]],
 [[2, 2, 2]],
 [[1, 1], [2]],
 [[1, 2], [2]]]
```

(continues on next page)

(continued from previous page)

```
sage: SST = SemistandardTableaux(3, max_entry=oo); SST
Semistandard tableaux of size 3
sage: SST[123]                                                              #␣
↪needs sage.modules
[[3, 4], [6]]

sage: SemistandardTableaux(max_entry=2)[11]                                 #␣
↪needs sage.modules
[[1, 1], [2]]

sage: SemistandardTableaux()[0]                                             #␣
↪needs sage.modules
[]
```

See also:

- *Tableaux*
- *Tableau*
- *SemistandardTableau*
- *StandardTableaux*
- *StandardTableau*

Element

alias of *SemistandardTableau*

class sage.combinat.tableau.**SemistandardTableaux_all**(*max_entry=None*)

Bases: *SemistandardTableaux*, DisjointUnionEnumeratedSets

All semistandard tableaux.

list()

class sage.combinat.tableau.**SemistandardTableaux_shape**(*p*, *max_entry=None*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed shape p with a given max entry.

A semistandard tableau with max entry i is required to have all its entries less or equal to i. It is not required to actually contain an entry i.

INPUT:

- `p` – a partition
- `max_entry` – the max entry; defaults to the size of `p`

cardinality(*algorithm='hook'*)

Return the cardinality of `self`.

INPUT:

- `algorithm` – (default: `'hook'`) any one of the following:
  - `'hook'` – use Stanley's hook length formula
  - `'sum'` – sum over the compositions of `max_entry` the number of semistandard tableau with `shape` and given weight vector

This is computed using *Stanley's hook length formula*:

$$f_\lambda = \prod_{u \in \lambda} \frac{n + c(u)}{h(u)}.$$

where n is the `max_entry`, $c(u)$ is the content of u, and $h(u)$ is the hook length of u. See [Sta-EC2] Corollary 7.21.4.

EXAMPLES:

```
sage: SemistandardTableaux([2,1]).cardinality()
8
sage: SemistandardTableaux([2,2,1]).cardinality()
75
sage: SymmetricFunctions(QQ).schur()([2,2,1]).expand(5)(1,1,1,1,1)  # cross␣
↪check       # needs sage.modules
75
sage: SemistandardTableaux([5]).cardinality()
126
sage: SemistandardTableaux([3,2,1]).cardinality()
896
sage: SemistandardTableaux([3,2,1], max_entry=7).cardinality()
2352
sage: SemistandardTableaux([6,5,4,3,2,1], max_entry=30).cardinality()
208361017592001331200
sage: ssts = [SemistandardTableaux(p, max_entry=6) for p in Partitions(5)]
sage: all(sst.cardinality() == sst.cardinality(algorithm='sum')             #␣
↪needs sage.modules
....:     for sst in ssts)
True
```

random_element()

Return a uniformly distributed random tableau of the given `shape` and `max_entry`.

Uses the algorithm from [Kra1999] based on the Novelli-Pak-Stoyanovskii bijection
http://www.sciencedirect.com/science/article/pii/0012365X9290368P

EXAMPLES:

```
sage: S = SemistandardTableaux([2, 2, 1, 1])
sage: S.random_element() in S
True
sage: S = SemistandardTableaux([2, 2, 1, 1], max_entry=7)
sage: S.random_element() in S
True
```

class sage.combinat.tableau.**SemistandardTableaux_shape_inf**(*p*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed shape p and no maximum entry.

class sage.combinat.tableau.**SemistandardTableaux_shape_weight**(*p*, *mu*)

Bases: *SemistandardTableaux_shape*

Semistandard tableaux of fixed shape p and weight μ.

cardinality()

Return the number of semistandard tableaux of the given shape and weight, as computed by `kostka_number` function of `symmetrica`.

EXAMPLES:

```
sage: # needs sage.modules
sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).cardinality()
1
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).cardinality()
2
```

list()

Return a list of all semistandard tableaux in `self` generated by symmetrica.

EXAMPLES:

```
sage: # needs sage.modules
sage: SemistandardTableaux([2,2], [2, 1, 1]).list()
[[[1, 1], [2, 3]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).list()
[[[1, 1], [2, 2], [3, 4]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).list()
[[[1, 1], [2, 2], [3, 3]]]
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

class sage.combinat.tableau.**SemistandardTableaux_size**(*n*, *max_entry=None*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed size n.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: SemistandardTableaux(3).cardinality()
19
sage: SemistandardTableaux(4).cardinality()
116
sage: SemistandardTableaux(4, max_entry=2).cardinality()
9
sage: SemistandardTableaux(4, max_entry=10).cardinality()
4225
sage: ns = list(range(1, 6))
sage: ssts = [ SemistandardTableaux(n) for n in ns ]
sage: all(sst.cardinality() == len(sst.list()) for sst in ssts)             #␣
↪needs sage.modules
True
```

random_element()

Generate a random *SemistandardTableau* with uniform probability.

The RSK algorithm gives a bijection between symmetric $k \times k$ matrices of nonnegative integers that sum to n and semistandard tableaux with size n and maximum entry k.

The number of $k \times k$ symmetric matrices of nonnegative integers having sum of elements on the diagonal i and sum of elements above the diagonal j is $\binom{k+i-1}{k-1}\binom{\binom{k}{2}+j-1}{\binom{k}{2}-1}$. We first choose the sum of the elements on the diagonal randomly weighted by the number of matrices having that trace. We then create random integer

vectors of length k having that sum and use them to generate a $k \times k$ diagonal matrix. Then we take a random integer vector of length $\binom{k}{2}$ summing to half the remainder and distribute it symmetrically to the remainder of the matrix.

Applying RSK to the random symmetric matrix gives us a pair of identical *SemistandardTableau* of which we choose the first.

EXAMPLES:

```
sage: SemistandardTableaux(6).random_element()  # random                    #␣
↪needs sage.modules
[[1, 1, 2], [3, 5, 5]]
sage: SemistandardTableaux(6, max_entry=7).random_element()  # random       #␣
↪needs sage.modules
[[2, 4, 4, 6, 6, 6]]
```

class sage.combinat.tableau.**SemistandardTableaux_size_inf**(*n*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed size n with no maximum entry.

list()

class sage.combinat.tableau.**SemistandardTableaux_size_weight**(*n*, *mu*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed size n and weight μ.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: SemistandardTableaux(3, [2,1]).cardinality()                          #␣
↪needs sage.modules
2
sage: SemistandardTableaux(4, [2,2]).cardinality()                          #␣
↪needs sage.modules
3
```

class sage.combinat.tableau.**StandardTableau**(*parent*, *t*, *check=True*)

Bases: *SemistandardTableau*

A class to model a standard tableau.

INPUT:

- `t` – a Tableau, a list of iterables, or an empty list

A standard tableau is a semistandard tableau whose entries are exactly the positive integers from 1 to n, where n is the size of the tableau.

EXAMPLES:

```
sage: t = StandardTableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
```

(continues on next page)

(continued from previous page)

```
sage: t.is_standard()
True
sage: StandardTableau([]) # The empty tableau
[]
sage: StandardTableau([[1,2,3],[4,5]]) in RowStandardTableaux()
True
```

When using code that will generate a lot of tableaux, it is more efficient to construct a StandardTableau from the appropriate `Parent` object:

```
sage: ST = StandardTableaux()
sage: ST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- *Tableaux*
- *Tableau*
- *SemistandardTableaux*
- *SemistandardTableau*
- *StandardTableaux*

check()

Check that `self` is a standard tableau.

dominates(*t*)

Return `True` if `self` dominates the tableau `t`.

That is, if the shape of the tableau restricted to k dominates the shape of `t` restricted to k, for $k = 1, 2, \ldots, n$.

When the two tableaux have the same shape, then this ordering coincides with the Bruhat ordering for the corresponding permutations.

INPUT:

- `t` – a tableau

EXAMPLES:

```
sage: s = StandardTableau([[1,2,3],[4,5]])
sage: t = StandardTableau([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
sage: all(StandardTableau(s).dominates(t) for t in StandardTableaux([3,2]))
True
sage: s.dominates([[1,2,3,4,5]])
False
```

down()

An iterator for all the standard tableaux that can be obtained from `self` by removing a cell. Note that this iterates just over a single tableau (or nothing if `self` is empty).

EXAMPLES:

```
sage: t = StandardTableau([[1,2],[3]])
sage: [x for x in t.down()]
[[[1, 2]]]
sage: t = StandardTableau([])
sage: [x for x in t.down()]
[]
```

down_list()

Return a list of all the standard tableaux that can be obtained from `self` by removing a cell. Note that this is just a singleton list if `self` is nonempty, and an empty list otherwise.

EXAMPLES:

```
sage: t = StandardTableau([[1,2],[3]])
sage: t.down_list()
[[[1, 2]]]
sage: t = StandardTableau([])
sage: t.down_list()
[]
```

is_standard()

Return `True` since `self` is a standard tableau.

EXAMPLES:

```
sage: StandardTableau([[1, 3], [2, 4]]).is_standard()
True
```

promotion(*n=None*)

Return the image of `self` under the promotion operator.

The promotion operator, applied to a standard tableau t, does the following:

Remove the letter n from t, thus leaving a hole where it used to be. Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of t. Fill 0 into the hole once jeu de taquin has completed. Finally, add 1 to each letter in the tableau. The resulting standard tableau is the image of t under the promotion operator.

This definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called "promotion" in [Sag2011] (p. 23) and in [Stan2009].

See the `promotion()` method for a more general operator.

EXAMPLES:

```
sage: ST = StandardTableaux(7)
sage: all( st.promotion().promotion_inverse() == st for st in ST ) # long time
True
sage: all( st.promotion_inverse().promotion() == st for st in ST ) # long time
True
sage: st = StandardTableau([[1,2,5],[3,4]])
sage: parent(st.promotion())
Standard tableaux
```

promotion_inverse(*n=None*)

Return the image of `self` under the inverse promotion operator. The optional variable m should be set to the size of `self` minus 1 for a minimal speedup; otherwise, it defaults to this number.

The inverse promotion operator, applied to a standard tableau t, does the following:

Remove the letter 1 from t, thus leaving a hole where it used to be. Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of t. Fill $n+1$ into this hole, where n is the size of t. Finally, subtract 1 from each letter in the tableau. This yields a new standard tableau.

This definition of inverse promotion is the map called "promotion" in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called "promotion" in [Hai1992] (p. 90).

See the `promotion_inverse()` method for a more general operator.

EXAMPLES:

```
sage: t = StandardTableau([[1,3],[2,4]])
sage: t.promotion_inverse()
[[1, 2], [3, 4]]
```

We check the equivalence of two definitions of inverse promotion on standard tableaux:

```
sage: ST = StandardTableaux(7)
sage: def bk_promotion_inverse7(st):
....:     st2 = st
....:     for i in range(1, 7):
....:         st2 = st2.bender_knuth_involution(i, check=False)
....:     return st2
sage: all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST )
↪# long time
True
```

standard_descents()

Return a list of the integers i such that i appears strictly further north than $i+1$ in `self` (this is not to say that i and $i+1$ must be in the same column). The list is sorted in increasing order.

EXAMPLES:

```
sage: StandardTableau( [[1,3,4],[2,5]] ).standard_descents()
[1, 4]
sage: StandardTableau( [[1,2],[3,4]] ).standard_descents()
[2]
sage: StandardTableau( [[1,2,5],[3,4],[6,7],[8],[9]] ).standard_descents()
[2, 5, 7, 8]
sage: StandardTableau( [] ).standard_descents()
[]
```

standard_major_index()

Return the major index of the standard tableau `self` in the standard meaning of the word. The major index is defined to be the sum of the descents of `self` (see *standard_descents()* for their definition).

EXAMPLES:

```
sage: StandardTableau( [[1,4,5],[2,6],[3]] ).standard_major_index()
8
sage: StandardTableau( [[1,2],[3,4]] ).standard_major_index()
2
sage: StandardTableau( [[1,2,3],[4,5]] ).standard_major_index()
3
```

standard_number_of_descents()

Return the number of all integers i such that i appears strictly further north than $i+1$ in `self` (this is not to say that i and $i+1$ must be in the same column). A list of these integers can be obtained using the *standard_descents()* method.

EXAMPLES:

```
sage: StandardTableau( [[1,2],[3,4],[5]] ).standard_number_of_descents()
2
sage: StandardTableau( [] ).standard_number_of_descents()
0
sage: tabs = StandardTableaux(5)
sage: all( t.standard_number_of_descents() == t.schuetzenberger_involution().
↪standard_number_of_descents() for t in tabs )
True
```

up()

An iterator for all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
```

up_list()

Return a list of all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
```

class sage.combinat.tableau.**StandardTableaux**(***kwds*)

Bases: *SemistandardTableaux*

A factory for the various classes of standard tableaux.

INPUT:

- Either a non-negative integer (possibly specified with the keyword `n`) or a partition.

OUTPUT:

- With no argument, the class of all standard tableaux
- With a non-negative integer argument, `n`, the class of all standard tableaux of size `n`
- With a partition argument, the class of all standard tableaux of that shape.

A standard tableau is a semistandard tableaux which contains each of the entries from 1 to `n` exactly once.

All classes of standard tableaux are iterable.

EXAMPLES:

```
sage: ST = StandardTableaux(3); ST
Standard tableaux of size 3
sage: ST.first()
[[1, 2, 3]]
sage: ST.last()
[[1], [2], [3]]
sage: ST.cardinality()
4
sage: ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
```

See also:

- *SemistandardTableau*
- *StandardTableau*
- *StandardSkewTableaux*

Element

alias of *StandardTableau*

class sage.combinat.tableau.**StandardTableaux_all**

Bases: *StandardTableaux*, DisjointUnionEnumeratedSets

All standard tableaux.

class sage.combinat.tableau.**StandardTableaux_shape**(*p*)

Bases: *StandardTableaux*

Semistandard tableaux of a fixed shape p.

cardinality()

Return the number of standard Young tableaux of this shape.

This method uses the so-called *hook length formula*, a formula for the number of Young tableaux associated with a given partition. The formula says the following: Let λ be a partition. For each cell c of the Young diagram of λ, let the *hook length* of c be defined as 1 plus the number of cells horizontally to the right of c plus the number of cells vertically below c. The number of standard Young tableaux of shape λ is then $n!$ divided by the product of the hook lengths of the shape of λ, where $n = |\lambda|$.

For example, consider the partition `[3,2,1]` of `6` with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with their respective hook lengths, we obtain:

```
5 3 1
3 1
1
```

The hook length formula returns

$$\frac{6!}{5 \cdot 3 \cdot 1 \cdot 3 \cdot 1 \cdot 1} = 16.$$

EXAMPLES:

```
sage: StandardTableaux([3,2,1]).cardinality()
16
sage: StandardTableaux([2,2]).cardinality()
2
sage: StandardTableaux([5]).cardinality()
1
```

(continues on next page)

(continued from previous page)

```
sage: StandardTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardTableaux([]).cardinality()
1
```

REFERENCES:

- http://mathworld.wolfram.com/HookLengthFormula.html

list()

Return a list of the standard Young tableaux of the specified shape.

EXAMPLES:

```
sage: StandardTableaux([2,2]).list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
sage: StandardTableaux([5]).list()
[[[1, 2, 3, 4, 5]]]
sage: StandardTableaux([3,2,1]).list()
[[[1, 4, 6], [2, 5], [3]],
 [[1, 3, 6], [2, 5], [4]],
 [[1, 2, 6], [3, 5], [4]],
 [[1, 3, 6], [2, 4], [5]],
 [[1, 2, 6], [3, 4], [5]],
 [[1, 4, 5], [2, 6], [3]],
 [[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 3, 4], [2, 6], [5]],
 [[1, 2, 4], [3, 6], [5]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 3, 5], [2, 4], [6]],
 [[1, 2, 5], [3, 4], [6]],
 [[1, 3, 4], [2, 5], [6]],
 [[1, 2, 4], [3, 5], [6]],
 [[1, 2, 3], [4, 5], [6]]]
```

random_element()

Return a random standard tableau of the given shape using the Greene-Nijenhuis-Wilf Algorithm.

EXAMPLES:

```
sage: t = StandardTableaux([2,2]).random_element()
sage: t.shape()
[2, 2]
sage: StandardTableaux([]).random_element()
[]
```

class sage.combinat.tableau.**StandardTableaux_size**(n)

Bases: *StandardTableaux*, DisjointUnionEnumeratedSets

Standard tableaux of fixed size n.

EXAMPLES:

```
sage: [ t for t in StandardTableaux(1) ]
[[[1]]]
sage: [ t for t in StandardTableaux(2) ]
[[[1, 2]], [[1], [2]]]
```

(continues on next page)

(continued from previous page)

```
sage: [ t for t in StandardTableaux(3) ]
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
sage: StandardTableaux(4)[:]
[[[1, 2, 3, 4]],
 [[1, 3, 4], [2]],
 [[1, 2, 4], [3]],
 [[1, 2, 3], [4]],
 [[1, 3], [2, 4]],
 [[1, 2], [3, 4]],
 [[1, 4], [2], [3]],
 [[1, 3], [2], [4]],
 [[1, 2], [3], [4]],
 [[1], [2], [3], [4]]]
```

cardinality()

Return the number of all standard tableaux of size `n`.

The number of standard tableaux of size n is equal to the number of involutions in the symmetric group S_n. This is a consequence of the symmetry of the RSK correspondence, that if $\sigma \mapsto (P, Q)$, then $\sigma^{-1} \mapsto (Q, P)$. For more information, see Wikipedia article Robinson-Schensted-Knuth_correspondence#Symmetry.

ALGORITHM:

The algorithm uses the fact that standard tableaux of size `n` are in bijection with the involutions of size `n`, (see page 41 in section 4.1 of [Ful1997]). For each number of fixed points, you count the number of ways to choose those fixed points multiplied by the number of perfect matchings on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
```

The cardinality can be computed without constructing all elements in this set, so this computation is fast (see also Issue #28273):

```
sage: StandardTableaux(500).cardinality()
42310756530860854995155175369O...22128599923665744392793725337 6
```

random_element()

Return a random `StandardTableau` with uniform probability.

This algorithm uses the fact that the Robinson-Schensted correspondence returns a pair of identical standard Young tableaux (SYTs) if and only if the permutation was an involution. Thus, generating a random SYT is equivalent to generating a random involution.

To generate an involution, we first need to choose its number of fixed points k (if the size of the involution is even, the number of fixed points will be even, and if the size is odd, the number of fixed points will be odd). To do this, we choose a random integer r between 0 and the number N of all involutions of size n. We then decompose the interval $\{1, 2, \ldots, N\}$ into subintervals whose lengths are the numbers of involutions of size n with respectively $0, 1, \ldots, \lfloor N/2 \rfloor$ fixed points. The interval in which our random integer r lies then decides how many fixed points our random involution will have. We then place those fixed points randomly and then compute a perfect matching (an involution without fixed points) on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(10).random_element() # random
[[1, 3, 6], [2, 5, 7], [4, 8], [9], [10]]
sage: StandardTableaux(0).random_element()
[]
sage: StandardTableaux(1).random_element()
[[1]]
```

class sage.combinat.tableau.**Tableau**(*parent*, *t*, *check=True*)

Bases: ClonableList

A class to model a tableau.

INPUT:

- t – a Tableau, a list of iterables, or an empty list

OUTPUT:

- A Tableau object constructed from t.

A tableau is abstractly a mapping from the cells in a partition to arbitrary objects (called entries). It is often represented as a finite list of nonempty lists (or, more generally an iterator of iterables) of weakly decreasing lengths. This list, in particular, can be empty, representing the empty tableau.

Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
sage: t.is_standard()
True

sage: Tableau([['a','c','b'],[],(2,1)]])
[['a', 'c', 'b'], [], (2, 1)]]
sage: Tableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a Tableau from the appropriate Parent object:

```
sage: T = Tableaux()
sage: T([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- *Tableaux*
- *SemistandardTableaux*
- *SemistandardTableau*
- *StandardTableaux*
- *StandardTableau*

add_entry(*cell*, *m*)

Return the result of setting the entry in cell `cell` equal to `m` in the tableau `self`.

This tableau has larger size than `self` if `cell` does not belong to the shape of `self`; otherwise, the tableau has the same shape as `self` and has the appropriate entry replaced.

INPUT:

- `cell` – a pair of nonnegative integers

OUTPUT:

The tableau `self` with the entry in cell `cell` set to `m`. This entry overwrites an existing entry if `cell` already belongs to `self`, or is added to the tableau if `cell` is a cocorner of the shape `self`. (Either way, the input is not modified.)

Note: Both coordinates of `cell` are interpreted as starting at 0. So, `cell == (0, 0)` corresponds to the northwesternmost cell.

EXAMPLES:

```
sage: s = StandardTableau([[1,2,5],[3,4]]); s.pp()
  1  2  5
  3  4
sage: t = s.add_entry( (1,2), 6); t.pp()
  1  2  5
  3  4  6
sage: t.category()
Category of elements of Standard tableaux
sage: s.add_entry( (2,0), 6).pp()
  1  2  5
  3  4
  6
sage: u = s.add_entry( (1,2), 3); u.pp()
  1  2  5
  3  4  3
sage: u.category()
Category of elements of Tableaux
sage: s.add_entry( (2,2),3)
Traceback (most recent call last):
...
IndexError: (2, 2) is not an addable cell of the tableau
```

anti_restrict(*n*)

Return the skew tableau formed by removing all of the cells from `self` that are filled with a number at most n.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.anti_restrict(1)
[[None, 2, 3], [4, 5]]
sage: t.anti_restrict(2)
[[None, None, 3], [4, 5]]
sage: t.anti_restrict(3)
[[None, None, None], [4, 5]]
sage: t.anti_restrict(4)
```

(continues on next page)

(continued from previous page)

```
[[None, None, None], [None, 5]]
sage: t.anti_restrict(5)
[[None, None, None], [None, None]]
```

atom()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).atom()
[2, 2]
sage: Tableau([[1,2,3],[4,5],[6]]).atom()
[3, 2, 1]
```

bender_knuth_involution(*k*, *rows=None*, *check=True*)

Return the image of `self` under the k-th Bender–Knuth involution, assuming `self` is a semistandard tableau.

Let T be a tableau, then a *lower free `k` in `T`* means a cell of T which is filled with the integer k and whose direct lower neighbor is not filled with the integer $k+1$ (in particular, this lower neighbor might not exist at all). Let an *upper free `k + 1` in `T`* mean a cell of T which is filled with the integer $k+1$ and whose direct upper neighbor is not filled with the integer k (in particular, this neighbor might not exist at all). It is clear that for any row r of T, the lower free k's and the upper free $k+1$'s in r together form a contiguous interval or r.

The *`k`-th Bender–Knuth switch at row `i`* changes the entries of the cells in this interval in such a way that if it used to have a entries of k and b entries of $k+1$, it will now have b entries of k and a entries of $k+1$. For fixed k, the k-th Bender–Knuth switches for different i commute. The composition of the k-th Bender–Knuth switches for all rows is called the *`k`-th Bender-Knuth involution*. This is used to show that the Schur functions defined by semistandard tableaux are symmetric functions.

INPUT:

- `k` – an integer
- `rows` – (Default `None`) When set to `None`, the method computes the k-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the k-th Bender–Knuth switches at row i over all i in `rows`. When set to an integer i, the method computes the k-th Bender–Knuth switch at row i. Note the indexing of the rows starts with 1.
- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

OUTPUT:

The image of `self` under either the k-th Bender–Knuth involution, the k-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = Tableau([[1,1,3,4,4,5,6,7],[2,2,4,6,7,7,7],[3,4,5,8,8,9],[6,6,7,10],
↪[7,8,8,11],[8]])
sage: t.bender_knuth_involution(1) == t
True
sage: t.bender_knuth_involution(2)
[[1, 1, 2, 4, 4, 5, 6, 7], [2, 3, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(3)
[[1, 1, 3, 3, 3, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
```

(continues on next page)

(continued from previous page)

```
sage: t.bender_knuth_involution(4)
[[1, 1, 3, 4, 5, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(5)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 5, 7, 7, 7], [3, 4, 6, 8, 8, 9], [5, 5,␣
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
```

The `rows` keyword can be an iterator:

```
sage: t.bender_knuth_involution(6, iter([1,2])) == t
False
sage: t.bender_knuth_involution(6, iter([3,4])) == t
True
```

The Bender–Knuth involution is an involution:

```
sage: T = SemistandardTableaux(shape=[3,1,1], max_entry=4)
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t      #␣
↪needs sage.modules
....:     for k in range(1, 5) for t in T)
True
```

The same holds for the single switches:

```
sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t ␣
↪          # needs sage.modules
....:     for k in range(1, 5) for j in range(1, 5) for t in T)
True
```

Locality of the Bender–Knuth involutions:

```
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l)           #␣
↪needs sage.modules
....:       == t.bender_knuth_involution(l).bender_knuth_involution(k)
....:     for k in range(1, 5) for l in range(1, 5) if abs(k - l) > 1
....:     for t in T)
True
```

Berenstein and Kirillov [KB1995] have shown that $(s_1 s_2)^6 = id$ (for tableaux of straight shape):

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k␣
↪+ 1)
sage: all(p(p(p(p(p(p(t,1),1),1),1),1),1) == t for t in T)                  #␣
↪needs sage.modules
True
```

However, $(s_2 s_3)^6 = id$ is false:

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k␣
↪+ 1)
sage: t = Tableau([[1,2,2],[3,4]])
sage: x = t
sage: for i in range(6): x = p(x, 2)
sage: x
[[1, 2, 3], [2, 4]]
sage: x == t
False
```

bump(*x*)

Insert `x` into `self` using Schensted's row-bumping (or row-insertion) algorithm.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.bump(1)
[[1, 1], [2], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(2)
[[1, 2, 2], [3]]
sage: t.bump(3)
[[1, 2, 3], [3]]
sage: t
[[1, 2], [3]]
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t.bump(2)
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
sage: t.bump(1)
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6], [5]]
```

bump_multiply(*other*)

Multiply two tableaux using Schensted's bump.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid. See pp. 11-12 of [Ful1997].

The same product operation is implemented in a different way in *slide_multiply()*.

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

catabolism()

Remove the top row of `self` and insert it back in using column Schensted insertion (starting with the largest letter).

EXAMPLES:

```
sage: Tableau([]).catabolism()
[]
sage: Tableau([[1,2,3,4,5]]).catabolism()
[[1, 2, 3, 4, 5]]
sage: Tableau([[1,1,3,3],[2,3],[3]]).catabolism()
```

(continues on next page)

(continued from previous page)

```
[[1, 1, 2, 3, 3, 3], [3]]
sage: Tableau([[1, 1, 2, 3, 3, 3], [3]]).catabolism()
[[1, 1, 2, 3, 3, 3, 3]]
```

catabolism_projector(*parts*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.catabolism_projector([[4,2,1]])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.catabolism_projector([[1]])
[]
sage: t.catabolism_projector([[2,1],[1]])
[]
sage: t.catabolism_projector([[1,1],[4,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

catabolism_sequence()

Perform *catabolism()* on `self` until it returns a tableau consisting of a single row.

EXAMPLES:

```
sage: t = Tableau([[1,2,3,4,5,6,8],[7,9]])
sage: t.catabolism_sequence()
[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
 [[1, 2, 3, 4, 5, 6, 7, 9], [8]],
 [[1, 2, 3, 4, 5, 6, 7, 8], [9]],
 [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
sage: Tableau([]).catabolism_sequence()
[[]]
```

cells()

Return a list of the coordinates of the cells of `self`.

Coordinates start at 0, so the northwesternmost cell (in English notation) has coordinates $(0, 0)$.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

cells_containing(*i*)

Return the list of cells in which the letter i appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (a, b), where both rows and columns are counted from 0 (so $a = 0$ means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```
sage: t = Tableau([[1,1,3],[2,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(6)
[]
```

(continues on next page)

(continued from previous page)

```
sage: t = Tableau([[1,1,2,4],[2,4,4],[4]])
sage: t.cells_containing(4)
[(2, 0), (1, 1), (1, 2), (0, 3)]

sage: t = Tableau([[1,1,2,8,9],[2,5,6,11],[3,7,7,13],[4,8,9],[5],[13],[14]])
sage: t.cells_containing(8)
[(3, 1), (0, 3)]

sage: Tableau([]).cells_containing(3)
[]
```

charge()

Return the charge of the reading word of `self`. See *charge()* for more information.

EXAMPLES:

```
sage: Tableau([[1,1],[2,2],[3]]).charge()
0
sage: Tableau([[1,1,3],[2,2]]).charge()
1
sage: Tableau([[1,1,2],[2],[3]]).charge()
1
sage: Tableau([[1,1,2],[2,3]]).charge()
2
sage: Tableau([[1,1,2,3],[2]]).charge()
2
sage: Tableau([[1,1,2,2],[3]]).charge()
3
sage: Tableau([[1,1,2,2,3]]).charge()
4
```

check()

Check that `self` is a valid straight-shape tableau.

EXAMPLES:

```
sage: t = Tableau([[1,1],[2]])
sage: t.check()

sage: t = Tableau([[None, None, 1], [2, 4], [3, 4, 5]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: a tableau must be a list of iterables of weakly decreasing length
```

cocharge()

Return the cocharge of the reading word of `self`. See *cocharge()* for more information.

EXAMPLES:

```
sage: Tableau([[1,1],[2,2],[3]]).cocharge()
4
sage: Tableau([[1,1,3],[2,2]]).cocharge()
3
sage: Tableau([[1,1,2],[2],[3]]).cocharge()
3
sage: Tableau([[1,1,2],[2,3]]).cocharge()
```

(continues on next page)

(continued from previous page)

```
2
sage: Tableau([[1,1,2,3],[2]]).cocharge()
2
sage: Tableau([[1,1,2,2],[3]]).cocharge()
1
sage: Tableau([[1,1,2,2,3]]).cocharge()
0
```

codegree(*e*, *multicharge=(0,)*)

Return the Brundan-Kleshchev-Wang [BKW2011] codegree of the standard tableau `self`.

The *codegree* of a tableau is an integer that is defined recursively by successively stripping off the number k, for $k = n, n-1, \ldots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and are above k in the diagram.

The codegree of the tableau T gives the degree of "dual" homogeneous basis element of the Graded Specht module that is indexed by T.

INPUT:

- `e` – the *quantum characteristic*
- `multicharge` – (default: `[0]`) the multicharge

OUTPUT:

The codegree of the tableau `self`, which is an integer.

EXAMPLES:

```
sage: StandardTableau([[1,3,5],[2,4]]).codegree(3)                              #␣
↪needs sage.groups
0
sage: StandardTableau([[1,2,5],[3,4]]).codegree(3)                              #␣
↪needs sage.groups
1
sage: StandardTableau([[1,2,5],[3,4]]).codegree(4)                              #␣
↪needs sage.groups
0
```

column_stabilizer()

Return the PermutationGroup corresponding to the column stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: # needs sage.groups
sage: cs = Tableau([[1,2,3],[4,5]]).column_stabilizer()
sage: cs.order() == factorial(2)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

components()

This function returns a list containing itself. It exists mainly for compatibility with *TableauTuple* as it allows constructions like the example below.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).conjugate()
[[1, 3], [2, 4]]
sage: c = StandardTableau([[1,2],[3,4]]).conjugate()
sage: c.parent()
Standard tableaux
```

content(*k*, *multicharge=[0]*)

Return the content of `k` in the standard tableau `self`.

The content of k is $c - r$ if k appears in row r and column c of the tableau.

The `multicharge` is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with *sage.combinat.tableau_tuple.TableauTuple()*.

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).content(3)
-1

sage: StandardTableau([[1,2],[3,4]]).content(6)
Traceback (most recent call last):
...
ValueError: 6 does not appear in tableau
```

corners()

Return the corners of the tableau `self`.

EXAMPLES:

```
sage: Tableau([[1, 4, 6], [2, 5], [3]]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Tableau([[1, 3], [2, 4]]).corners()
[(1, 1)]
```

degree(*e*, *multicharge=(0,)*)

Return the Brundan-Kleshchev-Wang [BKW2011] degree of `self`.

The *degree* is an integer that is defined recursively by successively stripping off the number k, for $k = n, n-1, \ldots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and which are below k in the diagram.

The degrees of the tableau T gives the degree of the homogeneous basis element of the graded Specht module that is indexed by T.

INPUT:

- `e` – the *quantum characteristic*
- `multicharge` – (default: `[0]`) the multicharge

OUTPUT:

The degree of the tableau `self`, which is an integer.

EXAMPLES:

```
sage: StandardTableau([[1,2,5],[3,4]]).degree(3)                              #␣
↪needs sage.groups
0
sage: StandardTableau([[1,2,5],[3,4]]).degree(4)                              #␣
↪needs sage.groups
1
```

descents()

Return a list of the cells `(i,j)` such that `self[i][j] > self[i-1][j]`.

Warning: This is not to be confused with the descents of a standard tableau.

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).descents()
[(1, 0)]
sage: Tableau( [[1,2],[3,4]] ).descents()
[(1, 0), (1, 1)]
sage: Tableau( [[1,2,3],[4,5]] ).descents()
[(1, 0), (1, 1)]
```

entries()

Return the tuple of all entries of `self`, in the order obtained by reading across the rows from top to bottom (in English notation).

EXAMPLES:

```
sage: t = Tableau([[1,3], [2]])
sage: t.entries()
(1, 3, 2)
```

entry(*cell*)

Return the entry of cell `cell` in the tableau `self`. Here, `cell` should be given as a tuple (i, j) of zero-based coordinates (so the northwesternmost cell in English notation is $(0, 0)$).

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: t.entry( (0,0) )
1
sage: t.entry( (1,1) )
4
```

evacuation(*n=None*, *check=True*)

Return the evacuation of the tableau `self`.

This is an alias for *schuetzenberger_involution()*.

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If n is specified, the underlying alphabet is assumed to be $[1, 2, \ldots, n]$. If no alphabet is specified, n is the maximal letter appearing in `self`.

INPUT:

- `n` – an integer specifying the maximal letter in the alphabet (optional)
- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check. (optional)

OUTPUT:

- a tableau, the evacuation of `self`

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,2]])
sage: t.evacuation(3)
[[2, 2, 3], [3, 3]]

sage: t = Tableau([[1,2,3],[4,5]])
sage: t.evacuation()
[[1, 2, 5], [3, 4]]

sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.evacuation()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

sage: t = Tableau([])
sage: t.evacuation()
[]

sage: t = StandardTableau([[1,2,3],[4,5]])
sage: s = t.evacuation()
sage: s.parent()
Standard tableaux
```

evaluation()

Return the weight of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a tableau T is the sequence $(a_1, a_2, a_3, \ldots)$, where a_k is the number of entries of T equal to k. This sequence contains only finitely many nonzero entries.

The weight of a tableau T is the same as the weight of the reading word of T, for any reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: Tableau([]).weight()
[]

sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

first_column_descent()

Return the first cell where `self` is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell (r, c) with r and c minimal such that the entry in position (r, c) is bigger than the entry in position $(r, c+1)$. If there is no such cell then `None` is returned - in this case the tableau is column strict.

OUTPUT:

The first cell which there is a descent or `None` if no such cell exists.

EXAMPLES:

```
sage: Tableau([[1,4,5],[2,3]]).first_column_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]).first_column_descent() is None
True
```

first_row_descent()

Return the first cell where the tableau `self` is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell (r, c) with r and c minimal such that the entry in position (r, c) is bigger than the entry in position $(r, c+1)$. If there is no such cell then `None` is returned - in this case the tableau is row strict.

OUTPUT:

The first cell which there is a descent or `None` if no such cell exists.

EXAMPLES:

```
sage: t = Tableau([[1,3,2],[4]]); t.first_row_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]).first_row_descent() is  None
True
```

flush()

Return the number of flush segments in `self`, as in [Sal2014].

Let $1 \leq i < k \leq r+1$ and suppose ℓ is the smallest integer greater than k such that there exists an ℓ-segment in the $(i+1)$-st row of T. A k-segment in the i-th row of T is called *flush* if the leftmost box in the k-segment and the leftmost box of the ℓ-segment are in the same column of T. If, however, no such ℓ exists, then this k-segment is said to be *flush* if the number of boxes in the k-segment is equal to θ_i, where $\theta_i = \lambda_i - \lambda_{i+1}$ and the shape of T is $\lambda = (\lambda_1 > \lambda_2 > \cdots > \lambda_r)$. Denote the number of flush k-segments in T by $\mathrm{flush}(T)$.

EXAMPLES:

```
sage: t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.flush()
3

sage: B = crystals.Tableaux("A4", shape=[4,3,2,1])                    #␣
↪needs sage.modules
sage: t = B[32].to_tableau()                                          #␣
↪needs sage.modules
sage: t.flush()                                                       #␣
↪needs sage.modules
4
```

height()

Return the height of `self`.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5]]).height()
2
sage: Tableau([[1,2,3]]).height()
1
```

(continues on next page)

(continued from previous page)

```
sage: Tableau([]).height()
0
```

hillman_grassl()

Return the image of the λ-array `self` under the Hillman-Grassl correspondence (as a *WeakReversePlanePartition*).

This relies on interpreting `self` as a λ-array in the sense of *hillman_grassl*.

Fix a partition λ (see *Partition()*). We draw all partitions and tableaux in English notation.

A *λ-array* will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape λ* (short: *λ-rpp*) will mean a λ-array whose entries weakly increase along each row and weakly increase along each column.

The Hillman-Grassl correspondence H is the map that sends a λ-array M to a λ-rpp $H(M)$ defined recursively as follows:

- If all entries of M are 0, then $H(M) = M$.
- Otherwise, let s be the index of the leftmost column of M containing a nonzero entry. Let r be the index of the bottommost nonzero entry in the s-th column of M. Let M' be the λ-array obtained from M by subtracting 1 from the (r, s)-th entry of M. Let $Q = (q_{i,j})$ be the image $H(M')$ (which is already defined by recursion).
- Define a sequence $((i_1, j_1), (i_2, j_2), \ldots, (i_n, j_n))$ of boxes in the diagram of λ (actually a lattice path made of southward and westward steps) as follows: Set $(i_1, j_1) = (r, \lambda_r)$ (the rightmost box in the r-th row of λ). If (i_k, j_k) is defined for some $k \geq 1$, then (i_{k+1}, j_{k+1}) is constructed as follows: If q_{i_k+1, j_k} is well-defined and equals q_{i_k, j_k}, then we set $(i_{k+1}, j_{k+1}) = (i_k + 1, j_k)$. Otherwise, if $j_k = s$, then the sequence ends here. Otherwise, we set $(i_{k+1}, j_{k+1}) = (i_k, j_k - 1)$.
- Let $H(M)$ be the array obtained from Q by adding 1 to the (i_k, j_k)-th entry of Q for each $k \in \{1, 2, \ldots, n\}$.

See [Gans1981] (Section 3) for this construction.

See also:

hillman_grassl() for the Hillman-Grassl correspondence as a standalone function.

hillman_grassl_inverse() for the inverse map.

EXAMPLES:

```
sage: a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
sage: A = a.hillman_grassl(); A
[[2, 2, 4], [2, 3, 4], [3, 5]]
sage: A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

insert_word(*w*, *left=False*)

Insert the word `w` into the tableau `self` letter by letter using Schensted insertion. By default, the word `w` is being processed from left to right, and the insertion used is row insertion. If the optional keyword `left` is set to `True`, the word `w` is being processed from right to left, and column insertion is used instead.

EXAMPLES:

```
sage: t0 = Tableau([])
sage: w = [1,1,2,3,3,3,3]
sage: t0.insert_word(w)
[[1, 1, 2, 3, 3, 3, 3]]
sage: t0.insert_word(w,left=True)
[[1, 1, 2, 3, 3, 3, 3]]
sage: w.reverse()
sage: t0.insert_word(w)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t0.insert_word(w,left=True)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t1 = Tableau([[1,3],[2]])
sage: t1.insert_word([4,5])
[[1, 3, 4, 5], [2]]
sage: t1.insert_word([4,5], left=True)
[[1, 3], [2, 5], [4]]
```

inversion_number()

Return the inversion number of `self`.

The inversion number is defined to be the number of inversions of `self` minus the sum of the arm lengths of the descents of `self` (see the *inversions()* and *descents()* methods for the relevant definitions).

Warning: This has none of the meanings in which the word "inversion" is used in the theory of standard tableaux.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversion_number()
0
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.inversion_number()
0
```

inversions()

Return a list of the inversions of `self`.

Let T be a tableau. An inversion is an attacking pair (c, d) of the shape of T (see *attacking_pairs()* for a definition of this) such that the entry of c in T is greater than the entry of d.

Warning: Do not mistake this for the inversions of a standard tableau.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversions()
[((1, 1), (0, 0))]
sage: t = Tableau([[1,4,3],[5,2],[2,6],[3]])
sage: t.inversions()
[((0, 1), (0, 2)), ((1, 0), (1, 1)), ((1, 1), (0, 0)), ((2, 1), (1, 0))]
```

is_column_increasing(*weak=False*)

Return `True` if the entries in each column are in increasing order, and `False` otherwise.

By default, this checks for strictly increasing columns. Set `weak` to `True` to test for weakly increasing columns.

EXAMPLES:

```
sage: T = Tableau([[1, 1, 3], [1, 2]])
sage: T.is_column_increasing(weak=True)
True
sage: T.is_column_increasing()
False
sage: Tableau([[2], [1]]).is_column_increasing(weak=True)
False
```

is_column_strict()

Return `True` if `self` is a column strict tableau and `False` otherwise.

A tableau is column strict if the entries in each column are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_column_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_column_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([[5, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([]).is_column_strict()
True
sage: Tableau([[1, 4, 2]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 5]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 3]]).is_column_strict()
False
```

is_increasing()

Return `True` if `self` is an increasing tableau and `False` otherwise.

A tableau is increasing if it is both row strict and column strict.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_increasing()
True
sage: Tableau([[1, 2], [2, 4]]).is_increasing()
True
sage: Tableau([[2, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[5, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[1, 2, 3], [2, 3], [3]]).is_increasing()
True
```

is_k_tableau(k)

Checks whether `self` is a valid weak k-tableau.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = Tableau([[1,1,3],[2,2],[3]])
sage: t.is_k_tableau(3)
False
```

is_key_tableau()

Return `True` if `self` is a key tableau or `False` otherwise.

A tableau is a *key tableau* if the set of entries in the j-th column is a subset of the set of entries in the $(j-1)$-st column.

REFERENCES:

- [LS1990]
- [Wil2010]

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,3],[3]])
sage: t.is_key_tableau()
True

sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_key_tableau()
False
```

is_rectangular()

Return `True` if the tableau `self` is rectangular and `False` otherwise.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).is_rectangular()
True
sage: Tableau([[1,2,3],[4,5],[6]]).is_rectangular()
False
sage: Tableau([]).is_rectangular()
True
```

is_row_increasing(*weak=False*)

Return `True` if the entries in each row are in increasing order, and `False` otherwise.

By default, this checks for strictly increasing rows. Set `weak` to `True` to test for weakly increasing rows.

EXAMPLES:

```
sage: T = Tableau([[1, 1, 3], [1, 2]])
sage: T.is_row_increasing(weak=True)
True
sage: T.is_row_increasing()
False
sage: Tableau([[2, 1]]).is_row_increasing(weak=True)
False
```

is_row_strict()

Return `True` if `self` is a row strict tableau and `False` otherwise.

A tableau is row strict if the entries in each row are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_row_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[5, 3], [2, 4]]).is_row_strict()
False
```

is_semistandard()

Return `True` if `self` is a semistandard tableau, and `False` otherwise.

A tableau is semistandard if its rows weakly increase and its columns strictly increase.

EXAMPLES:

```
sage: Tableau([[1,1],[1,2]]).is_semistandard()
False
sage: Tableau([[1,2],[1,2]]).is_semistandard()
False
sage: Tableau([[1,1],[2,2]]).is_semistandard()
True
sage: Tableau([[1,2],[2,3]]).is_semistandard()
True
sage: Tableau([[4,1],[3,2]]).is_semistandard()
False
```

is_standard()

Return `True` if `self` is a standard tableau and `False` otherwise.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_standard()
True
sage: Tableau([[1, 2], [2, 4]]).is_standard()
False
sage: Tableau([[2, 3], [2, 4]]).is_standard()
False
sage: Tableau([[5, 3], [2, 4]]).is_standard()
False
```

k_weight(k)

Return the k-weight of `self`.

A tableau has k-weight $\alpha = (\alpha_1, ..., \alpha_n)$ if there are exactly α_i distinct residues for the cells occupied by the letter i for each i. The residue of a cell in position (a, b) is $a - b$ modulo $k + 1$.

This definition is the one used in [Ive2012] (p. 12).

EXAMPLES:

```
sage: Tableau([[1,2],[2,3]]).k_weight(1)
[1, 1, 1]
sage: Tableau([[1,2],[2,3]]).k_weight(2)
[1, 2, 1]
sage: t = Tableau([[1,1,1,2,5],[2,3,6],[3],[4]])
sage: t.k_weight(1)
```

(continues on next page)

(continued from previous page)

```
[2, 1, 1, 1, 1, 1]
sage: t.k_weight(2)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(3)
[3, 1, 2, 1, 1, 1]
sage: t.k_weight(4)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(5)
[3, 2, 2, 1, 1, 1]
```

lambda_catabolism(*part*)

Return the `part`-catabolism of `self`, where `part` is a partition (which can be just given as an array).

For a partition λ and a tableau T, the λ-catabolism of T is defined by performing the following steps.

1. Truncate the parts of λ so that λ is contained in the shape of T. Let m be the length of this partition.
2. Let T_a be the first m rows of T, and T_b be the remaining rows.
3. Let S_a be the skew tableau T_a/λ.
4. Concatenate the reading words of S_a and T_b, and insert into a tableau.

EXAMPLES:

```
sage: Tableau([[1,1,3],[2,4,5]]).lambda_catabolism([2,1])
[[3, 5], [4]]
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.lambda_catabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.lambda_catabolism([2,1])
[[3, 3, 3, 3]]
sage: t.lambda_catabolism([4,2,1])
[]
sage: t.lambda_catabolism([5,1])
[[3, 3]]
sage: t.lambda_catabolism([4,1])
[[3, 3]]
```

last_letter_lequal(*tab2*)

Return `True` if `self` is less than or equal to `tab2` in the last letter ordering.

EXAMPLES:

```
sage: st = StandardTableaux([3,2])
sage: f = lambda b: 1 if b else 0
sage: matrix([[f(t1.last_letter_lequal(t2)) for t2 in st] for t1 in st])    #␣
↪needs sage.modules
[1 1 1 1 1]
[0 1 1 1 1]
[0 0 1 1 1]
[0 0 0 1 1]
[0 0 0 0 1]
```

left_key_tableau()

Return the left key tableau of `self`.

The left key tableau of a tableau T is the key tableau whose entries are weakly lesser than the corresponding entries in T, and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

ALGORITHM:

The following algorithm follows [Wil2010]. Note that if T is a key tableau then the output of the algorithm is T.

To compute the left key tableau L of a tableau T we iterate over the columns of T. Let T_j be the j-th column of T and iterate over the entries in T_j from bottom to top. Initialize the corresponding entry k in L as the largest entry in T_j. Scan the columns to the left of T_j and with each column update k to be the lowest entry in that column which is weakly less than k. Update T_j and all columns to the left by removing all scanned entries.

See also:

- *is_key_tableau()*

EXAMPLES:

```
sage: t = Tableau([[1,2],[2,3]])
sage: t.left_key_tableau()
[[1, 1], [2, 2]]
sage: t = Tableau([[1,1,2,4],[2,3,3],[4],[5]])
sage: t.left_key_tableau()
[[1, 1, 1, 2], [2, 2, 2], [4], [5]]
```

leq(*secondtab*)

Check whether each entry of `self` is less-or-equal to the corresponding entry of a further tableau `secondtab`.

INPUT:

- `secondtab` – a tableau of the same shape as `self`

EXAMPLES:

```
sage: T = Tableau([[1, 2], [3]])
sage: S = Tableau([[1, 3], [3]])
sage: G = Tableau([[2, 1], [4]])
sage: H = Tableau([[1, 2], [4]])
sage: T.leq(S)
True
sage: T.leq(T)
True
sage: T.leq(G)
False
sage: T.leq(H)
True
sage: S.leq(T)
False
sage: S.leq(G)
False
sage: S.leq(H)
False
```

(continues on next page)

(continued from previous page)

```
sage: G.leq(H)
False
sage: H.leq(G)
False
```

level()

Return the level of `self`, which is always 1.

This function exists mainly for compatibility with *TableauTuple*.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5]]).level()
1
```

major_index()

Return the major index of `self`.

The major index of a tableau T is defined to be the sum of the number of descents of `T` (defined in *descents()*) with the sum of their legs' lengths.

Warning: This is not to be confused with the major index of a standard tableau.

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).major_index()
1
sage: Tableau( [[1,2],[3,4]] ).major_index()
2
```

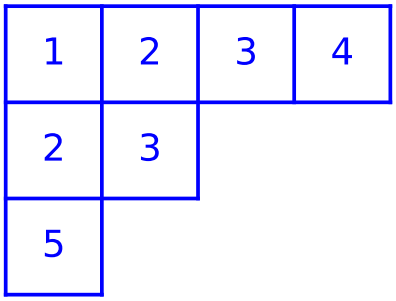
If the major index would be defined in the sense of standard tableaux theory, then the following would give 3 for a result:

```
sage: Tableau( [[1,2,3],[4,5]] ).major_index()
2
```

plot(*descents=False*)

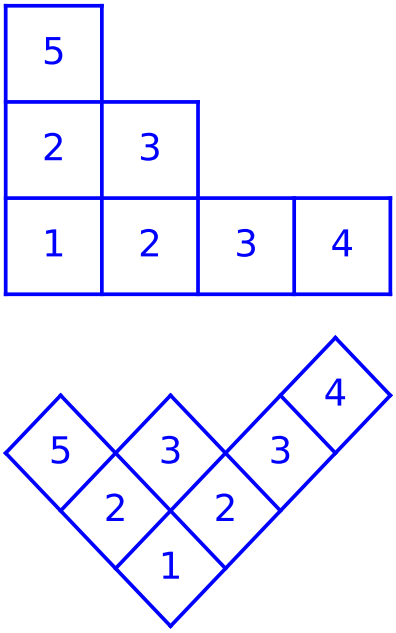
Return a plot `self`.

If English notation is set then the first row of the tableau is on the top:



If French notation is set, the first row of the tableau is on the bottom:

If Russian notation is set, we tilt the French notation by 45 degrees:



INPUT:

- `descents` – boolean (default: `False`); if `True`, then the descents are marked in the tableau; only valid if `self` is a standard tableau

EXAMPLES:

```
sage: t = Tableau([[1,2,4],[3]])
sage: t.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 11 graphics primitives
sage: t.plot(descents=True)                                                 #␣
↪needs sage.plot
Graphics object consisting of 12 graphics primitives

sage: t = Tableau([[2,2,4],[3]])
sage: t.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 11 graphics primitives
sage: t.plot(descents=True)                                                 #␣
↪needs sage.plot
Traceback (most recent call last):
...
ValueError: the tableau must be standard for 'descents=True'
```

pp()

Pretty print a string of the tableau.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[3,4],[5]])
sage: T.pp()
  1  2  3
  3  4
  5
```

(continues on next page)

(continued from previous page)

```
sage: Tableaux.options.convention="french"
sage: T.pp()
  5
  3  4
  1  2  3
sage: Tableaux.options.convention="russian"
sage: T.pp()
 5    4    3
    3    2
      1
sage: Tableaux.options._reset()
```

promotion(*n*)

Return the image of `self` under the promotion operator.

Warning: You might know this operator as the inverse promotion operator – literature does not agree on the name. You might also be looking for the Lapointe-Lascoux-Morse promotion operator (*promotion_operator()*).

The promotion operator, applied to a tableau t, does the following:

Iterate over all letters $n+1$ in the tableau t, from left to right. For each of these letters, do the following:

- Remove the letter from t, thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of t.
- Fill 0 into the hole once jeu de taquin has completed.

Once this all is done, add 1 to each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all $\leq n+1$, this is the usual promotion operator defined on this class.

When `self` is a standard tableau of size `n + 1`, this definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called "promotion" in [Sag2011] (p. 23) and in [Stan2009].

Warning: To my (Darij's) knowledge, the fact that the above promotion operator really is the inverse of the "inverse promotion operator" *promotion_inverse()* for semistandard tableaux has never been proven in literature. Corrections are welcome.

REFERENCES:

- [Hai1992]
- [Sag2011]

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,1,1],[2,2,3],[3,4,4]])
sage: t.promotion(3)
```

(continues on next page)

(continued from previous page)

```
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]

sage: t = Tableau([[1,2],[2]])
sage: t.promotion(3)
[[2, 3], [3]]

sage: t = Tableau([[1,1,3],[2,2]])
sage: t.promotion(2)
[[1, 2, 2], [3, 3]]

sage: t = Tableau([[1,1,3],[2,3]])
sage: t.promotion(2)
[[1, 1, 2], [2, 3]]

sage: t = Tableau([])
sage: t.promotion(2)
[]
```

promotion_inverse(n)

Return the image of `self` under the inverse promotion operator.

Warning: You might know this operator as the promotion operator (without "inverse") – literature does not agree on the name.

The inverse promotion operator, applied to a tableau t, does the following:

Iterate over all letters 1 in the tableau t, from right to left. For each of these letters, do the following:

- Remove the letter from t, thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of t.
- Fill $n + 2$ into the hole once jeu de taquin has completed.

Once this all is done, subtract 1 from each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all $\leq n + 1$, this is the usual inverse promotion operator defined on this class.

When `self` is a standard tableau of size `n + 1`, this definition of inverse promotion is the map called "promotion" in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called "promotion" in [Hai1992] (p. 90).

Warning: To my (Darij's) knowledge, the fact that the above "inverse promotion operator" really is the inverse of the promotion operator *promotion()* for semistandard tableaux has never been proven in literature. Corrections are welcome.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion_inverse(2)
[[1, 2], [2, 3]]

sage: t = Tableau([[1,2],[2,3]])
```

(continues on next page)

(continued from previous page)

```
sage: t.promotion_inverse(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,2,5],[3,3,6],[4,7]])
sage: t.promotion_inverse(8)
[[1, 2, 4], [2, 5, 9], [3, 6]]

sage: t = Tableau([])
sage: t.promotion_inverse(2)
[]
```

promotion_operator(*i*)

Return a list of semistandard tableaux obtained by the i-th Lapointe-Lascoux-Morse promotion operator from the semistandard tableau `self`.

Warning: This is not Schuetzenberger's jeu de taquin promotion! For the latter, see *promotion()* and *promotion_inverse()*.

This operator is defined by taking the maximum entry m of T, then adding a horizontal i-strip to T in all possible ways, each time filling this strip with $m+1$'s, and finally letting the permutation $\sigma_1\sigma_2\cdots\sigma_m = (2,3,\ldots,m+1,1)$ act on each of the resulting tableaux via the Lascoux-Schuetzenberger action (*symmetric_group_action_on_values()*). This method returns the list of all resulting tableaux. See [LLM2003] for the purpose of this operator.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.promotion_operator(1)
[[[1, 2, 4], [3]], [[1, 2], [3, 4]], [[1, 2], [3], [4]]]
sage: t.promotion_operator(2)
[[[1, 1, 2, 4], [3]],
 [[1, 1, 4], [2, 3]],
 [[1, 1, 2], [3], [4]],
 [[1, 1], [2, 3], [4]]]
sage: Tableau([[1]]).promotion_operator(2)
[[[1, 1, 2]], [[1, 1], [2]]]
sage: Tableau([[1,1],[2]]).promotion_operator(3)
[[[1, 1, 1, 2, 3], [2]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1], [2, 2], [3]]]
```

The example from [LLM2003] p. 12:

```
sage: Tableau([[1,1],[2,2]]).promotion_operator(3)
[[[1, 1, 1, 3, 3], [2, 2]],
 [[1, 1, 1, 3], [2, 2], [3]],
 [[1, 1, 1], [2, 2], [3, 3]]]
```

raise_action_from_words(*f*, **args*)

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: import functools
```

(continues on next page)

(continued from previous page)

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: f = functools.partial(t.raise_action_from_words, symmetric_group_action_
↪on_values)
sage: f([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: f([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
sage: f([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

reading_word_permutation()

Return the permutation obtained by reading the entries of the standardization of `self` row by row, starting with the bottommost row (in English notation).

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).reading_word_permutation()
[3, 4, 1, 2]
```

Check that Issue #14724 is fixed:

```
sage: SemistandardTableau([[1,1]]).reading_word_permutation()
[1, 2]
```

reduced_column_word()

Return the lexicographically minimal reduced expression for the permutation that maps the conjugate of the `initial_tableau()` to `self`.

Ths reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the columns of the tableau in order from top to bottom.

EXAMPLES:

```
sage: StandardTableau([[1,4,6],[2,5],[3]]).reduced_column_word()
[]
sage: StandardTableau([[1,4,5],[2,6],[3]]).reduced_column_word()
[5]
sage: StandardTableau([[1,3,6],[2,5],[4]]).reduced_column_word()
[3]
sage: StandardTableau([[1,3,5],[2,6],[4]]).reduced_column_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_column_word()
[3, 2, 5]
```

reduced_lambda_catabolism(*part*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.reduced_lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.reduced_lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([2,1])
```

(continues on next page)

(continued from previous page)

```
[[3, 3, 3, 3]]
sage: t.reduced_lambda_catabolism([4,2,1])
[]
sage: t.reduced_lambda_catabolism([5,1])
0
sage: t.reduced_lambda_catabolism([4,1])
0
```

reduced_row_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_tableau()` to `self`.

Ths reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau in order from top to bottom.

EXAMPLES:

```
sage: StandardTableau([[1,2,3],[4,5],[6]]).reduced_row_word()
[]
sage: StandardTableau([[1,2,3],[4,6],[5]]).reduced_row_word()
[5]
sage: StandardTableau([[1,2,4],[3,6],[5]]).reduced_row_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_row_word()
[3, 5, 4]
sage: StandardTableau([[1,2,6],[3,5],[4]]).reduced_row_word()
[3, 4, 5, 4]
```

residue(*k*, *e*, *multicharge=(0,)*)

Return the residue of the integer `k` in the tableau `self`.

The *residue* of k in a standard tableau is $c - r + m$ in $\mathbf{Z}/e\mathbf{Z}$, where k appears in row r and column c of the tableau with multicharge m.

INPUT:

- `k` – an integer in $\{1, 2, \ldots, n\}$
- `e` – an integer in $\{0, 2, 3, 4, 5, \ldots\}$
- `multicharge` – (default: `[0]`) a list of length 1

Here n is its size of `self`.

The `multicharge` is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

OUTPUT:

The residue in $\mathbf{Z}/e\mathbf{Z}$.

EXAMPLES:

```
sage: StandardTableau([[1,2,5],[3,4]]).residue(1,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(2,3)
1
sage: StandardTableau([[1,2,5],[3,4]]).residue(3,3)
2
```

(continues on next page)

(continued from previous page)

```
sage: StandardTableau([[1,2,5],[3,4]]).residue(4,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(5,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(6,3)
Traceback (most recent call last):
...
ValueError: 6 does not appear in the tableau
```

residue_sequence(*e*, *multicharge=(0,)*)

Return the *sage.combinat.tableau_residues.ResidueSequence* of the tableau `self`.

INPUT:

- `e` – an integer in $\{0, 2, 3, 4, 5, \ldots\}$
- `multicharge` – (default: `[0]`) a sequence of integers of length 1

The *multicharge* is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

OUTPUT:

The corresponding residue sequence of the tableau; see `ResidueSequence`.

EXAMPLES:

```
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(2)                #␣
↪needs sage.groups
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(3)                #␣
↪needs sage.groups
3-residue sequence (0,1,2,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(4)                #␣
↪needs sage.groups
4-residue sequence (0,1,3,0) with multicharge (0)
```

restrict(*n*)

Return the restriction of the semistandard tableau `self` to `n`. If possible, the restricted tableau will have the same parent as this tableau.

If T is a semistandard tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than n from T.

Note: If only the shape of the restriction, rather than the whole restriction, is needed, then the faster method *restriction_shape()* is preferred.

EXAMPLES:

```
sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: StandardTableau([[1,2],[3],[4]]).restrict(2)
[[1, 2]]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)
[]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(2)
[[1, 2], [2]]
```

(continues on next page)

(continued from previous page)

```
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(3)
[[1, 2, 3], [2], [3]]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(5)
[[1, 2, 3], [2, 4, 4], [3]]
```

If possible the restricted tableau will belong to the same category as the original tableau:

```
sage: S = StandardTableau([[1,2,4,7],[3,5],[6]]); S.category()
Category of elements of Standard tableaux
sage: S.restrict(4).category()
Category of elements of Standard tableaux
sage: SS=StandardTableaux([4,2,1])([[1,2,4,7],[3,5],[6]]); SS.category()
Category of elements of Standard tableaux of shape [4, 2, 1]
sage: SS.restrict(4).category()
Category of elements of Standard tableaux

sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: Tableau([[1,2],[3],[4]]).restrict(2)
[[1, 2]]
sage: SemistandardTableau([[1,1],[2]]).restrict(1)
[[1, 1]]
sage: _.category()
Category of elements of Semistandard tableaux
```

restriction_shape(*n*)

Return the shape of the restriction of the semistandard tableau `self` to `n`.

If T is a semistandard tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```
sage: Tableau([[1,2],[2,3],[3,4]]).restriction_shape(3)
[2, 2, 1]
sage: StandardTableau([[1,2],[3],[4],[5]]).restriction_shape(2)
[2]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(0)
[]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(2)
[1, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(3)
[3, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(5)
[4, 3]

sage: all( T.restriction_shape(i) == T.restrict(i).shape()
....:      for T in StandardTableaux(5) for i in range(1, 5) )
True
```

reverse_bump(*loc*)

Reverse row bump the entry of `self` at the specified location `loc` (given as a row index or a corner `(r, c)` of the tableau).

This is the reverse of Schensted's row-insertion algorithm. See Section 1.1, page 8, of Fulton's [Ful1997].

INPUT:

- `loc` – Can be either of the following:
  - The coordinates `(r, c)` of the square to reverse-bump (which must be a corner of the tableau);
  - The row index `r` of this square.

  Note that both `r` and `c` are 0-based, i.e., the topmost row and the leftmost column are the 0-th row and the 0-th column.

OUTPUT:

An ordered pair consisting of:

1. The resulting (smaller) tableau;
2. The entry bumped out at the end of the process.

See also:

bump()

EXAMPLES:

This is the reverse of Schensted's bump:

```
sage: T = Tableau([[1, 1, 2, 2, 4], [2, 3, 3], [3, 4], [4]])
sage: T.reverse_bump(2)
([[1, 1, 2, 3, 4], [2, 3, 4], [3], [4]], 2)
sage: T == T.reverse_bump(2)[0].bump(2)
True
sage: T.reverse_bump((3, 0))
([[1, 2, 2, 2, 4], [3, 3, 3], [4, 4]], 1)
```

Some errors caused by wrong input:

```
sage: T.reverse_bump((3, 1))
Traceback (most recent call last):
...
ValueError: invalid corner
sage: T.reverse_bump(4)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: Tableau([[2, 2, 1], [3, 3]]).reverse_bump(0)
Traceback (most recent call last):
...
ValueError: reverse bumping is only defined for semistandard tableaux
```

Some edge cases:

```
sage: Tableau([[1]]).reverse_bump(0)
([], 1)
sage: Tableau([[1,1]]).reverse_bump(0)
([[1]], 1)
sage: Tableau([]).reverse_bump(0)
Traceback (most recent call last):
...
IndexError: list index out of range
```

Note: Reverse row bumping is only implemented for tableaux with weakly increasing and strictly increasing columns (though the tableau does not need to be an instance of class *SemistandardTableau*).

right_key_tableau()

Return the right key tableau of `self`.

The right key tableau of a tableau T is a key tableau whose entries are weakly greater than the corresponding entries in T, and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

ALGORITHM:

The following algorithm follows [Wil2010]. Note that if T is a key tableau then the output of the algorithm is T.

To compute the right key tableau R of a tableau T we iterate over the columns of T. Let T_j be the j-th column of T and iterate over the entries in T_j from bottom to top. Initialize the corresponding entry k in R to be the largest entry in T_j. Scan the bottom of each column of T to the right of T_j, updating k to be the scanned entry whenever the scanned entry is weakly greater than k. Update T_j and all columns to the right by removing all scanned entries.

See also:

- *is_key_tableau()*

EXAMPLES:

```
sage: t = Tableau([[1,2],[2,3]])
sage: t.right_key_tableau()
[[2, 2], [3, 3]]
sage: t = Tableau([[1,1,2,4],[2,3,3],[4],[5]])
sage: t.right_key_tableau()
[[2, 2, 2, 4], [3, 4, 4], [4], [5]]
```

rotate_180()

Return the tableau obtained by rotating `self` by 180 degrees.

This only works for rectangular tableaux.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).rotate_180()
[[4, 3], [2, 1]]
```

row_stabilizer()

Return the PermutationGroup corresponding to the row stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: # needs sage.groups
sage: rs = Tableau([[1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
```

(continues on next page)

(continued from previous page)

```
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs = Tableau([[1, 2],[3]]).row_stabilizer()
sage: PermutationGroupElement([(1,2),(3,)]) in rs
True
sage: rs.one().domain()
[1, 2, 3]
sage: rs = Tableau([[1],[2],[3]]).row_stabilizer()
sage: rs.order()
1
sage: rs = Tableau([[2,4,5],[1,3]]).row_stabilizer()
sage: rs.order()
12
sage: rs = Tableau([]).row_stabilizer()
sage: rs.order()
1
```

schensted_insert(*i*, *left=False*)

Insert `i` into `self` using Schensted's row-bumping (or row-insertion) algorithm.

INPUT:

- `i` – a number to insert
- `left` – (default: `False`) boolean; if set to `True`, the insertion will be done from the left. That is, if one thinks of the algorithm as appending a letter to the reading word of `self`, we append the letter to the left instead of the right

EXAMPLES:

```
sage: t = Tableau([[3,5],[7]])
sage: t.schensted_insert(8)
[[3, 5, 8], [7]]
sage: t.schensted_insert(8, left=True)
[[3, 5], [7], [8]]
```

schuetzenberger_involution(*n=None*, *check=True*)

Return the Schuetzenberger involution of the tableau `self`.

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If n is specified, the underlying alphabet is assumed to be $[1, 2, \ldots, n]$. If no alphabet is specified, n is the maximal letter appearing in `self`.

INPUT:

- `n` – an integer specifying the maximal letter in the alphabet (optional)
- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check. (optional)

OUTPUT:

- a tableau, the Schuetzenberger involution of `self`

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,2]])
sage: t.schuetzenberger_involution(3)
[[2, 2, 3], [3, 3]]
```

(continues on next page)

(continued from previous page)

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: t.schuetzenberger_involution()
[[1, 2, 5], [3, 4]]

sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.schuetzenberger_involution()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

sage: t = Tableau([])
sage: t.schuetzenberger_involution()
[]

sage: t = StandardTableau([[1,2,3],[4,5]])
sage: s = t.schuetzenberger_involution()
sage: s.parent()
Standard tableaux
```

seg()

Return the total number of segments in `self`, as in [Sal2014].

Let T be a tableaux. We define a *k-segment* of T (in the i-th row) to be a maximal consecutive sequence of k-boxes in the i-th row for any $i + 1 \leq k \leq r + 1$. Denote the total number of k-segments in T by $\mathrm{seg}(T)$.

REFERENCES:

- [Sal2014]

EXAMPLES:

```
sage: t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.seg()
6

sage: B = crystals.Tableaux("A4", shape=[4,3,2,1])                    #␣
↪needs sage.modules
sage: t = B[31].to_tableau()                                          #␣
↪needs sage.modules
sage: t.seg()                                                         #␣
↪needs sage.modules
3
```

shape()

Return the shape of a tableau `self`.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5],[6]]).shape()
[3, 2, 1]
```

size()

Return the size of the shape of the tableau `self`.

EXAMPLES:

```
sage: Tableau([[1, 4, 6], [2, 5], [3]]).size()
6
```

(continues on next page)

(continued from previous page)

```
sage: Tableau([[1, 3], [2, 4]]).size()
4
```

slide_multiply(*other*)

Multiply two tableaux using jeu de taquin.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid.

See pp. 15 of [Ful1997].

The same product operation is implemented in a different way in *bump_multiply()*.

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.slide_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

socle()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).socle()
2
sage: Tableau([[1,2,3,4]]).socle()
4
```

standardization(*check=True*)

Return the standardization of `self`, assuming `self` is a semistandard tableau.

The standardization of a semistandard tableau T is the standard tableau $\mathrm{st}(T)$ of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T.

The standardization of a word w can be formed by replacing all 1's in w by $1, 2, \ldots, k_1$ from left to right, all 2's in w by $k_1 + 1, k_1 + 2, \ldots, k_2$, and repeating for all letters which appear in w. See also `Word.standard_permutation()`.

INPUT:

- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

EXAMPLES:

```
sage: t = Tableau([[1,3,3,4],[2,4,4],[5,16]])
sage: t.standardization()
[[1, 3, 4, 7], [2, 5, 6], [8, 9]]
```

Standard tableaux are fixed under standardization:

```
sage: all((t == t.standardization() for t in StandardTableaux(6)))
True
sage: t = Tableau([])
sage: t.standardization()
[]
```

The reading word of the standardization is the standardization of the reading word:

```
sage: T = SemistandardTableaux(shape=[5,2,2,1], max_entry=4)
sage: all(t.to_word().standard_permutation() == t.standardization().reading_
↪word_permutation() for t in T) # long time
True
```

sulzgruber_correspondence()

Return the image of the λ-array `self` under the Sulzgruber correspondence (as a *WeakReversePlanePartition*).

This relies on interpreting `self` as a λ-array in the sense of *hillman_grassl*. See *hillman_grassl* for definitions of the objects involved.

The Sulzgruber correspondence is the map Φ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ^{-1} from [Pak2002] Section 5. It is denoted by $\mathcal{RSK}$ in [Hopkins2017]. It is the inverse of the Pak correspondence (`pak_correspondence()`). The following description of the Sulzgruber correspondence follows [Hopkins2017] (which denotes it by $\mathcal{RSK}$):

Fix a partition λ (see *Partition()*). We draw all partitions and tableaux in English notation.

A *λ-array* will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape λ* (short: *λ-rpp*) will mean a λ-array whose entries weakly increase along each row and weakly increase along each column.

We shall also use the following notation: If (u, v) is a cell of λ, and if π is a λ-rpp, then:

- the *lower bound* of π at (u, v) (denoted by $\pi_{<(u,v)}$) is defined to be $\max\{\pi_{u-1,v}, \pi_{u,v-1}\}$ (where $\pi_{0,v}$ and $\pi_{u,0}$ are understood to mean 0).
- the *upper bound* of π at (u, v) (denoted by $\pi_{>(u,v)}$) is defined to be $\min\{\pi_{u+1,v}, \pi_{u,v+1}\}$ (where $\pi_{i,j}$ is understood to mean $+\infty$ if (i, j) is not in λ; thus, the upper bound at a corner cell is $+\infty$).
- *toggling* π at (u, v) means replacing the entry $\pi_{u,v}$ of π at (u, v) by $\pi_{<(u,v)} + \pi_{>(u,v)} - \pi_{u,v}$ (this is well-defined as long as (u, v) is not a corner of λ).

Note that every λ-rpp π and every cell (u, v) of λ satisfy $\pi_{<(u,v)} \leq \pi_{u,v} \leq \pi_{>(u,v)}$. Note that toggling a λ-rpp (at a cell that is not a corner) always results in a λ-rpp. Also, toggling is an involution).

The Pak correspondence ξ_λ sends a λ-rpp π to a λ-array $\xi_\lambda(\pi)$. It is defined by recursion on λ (that is, we assume that ξ_μ is already defined for every partition μ smaller than λ), and its definition proceeds as follows:

- If $\lambda = \varnothing$, then ξ_λ is the obvious bijection sending the only $\varnothing$-rpp to the only $\varnothing$-array.
- Pick any corner $c = (i, j)$ of λ, and let μ be the result of removing this corner c from the partition λ. (The exact choice of c is immaterial.)
- Let π' be what remains of π when the corner cell c is removed.
- For each positive integer k such that $(i - k, j - k)$ is a cell of λ, toggle π' at $(i - k, j - k)$. (All these togglings commute, so the order in which they are made is immaterial.)
- Let $M = \xi_\mu(\pi')$.
- Extend the μ-array M to a λ-array M' by adding the cell c and writing the number $\pi_{i,j} - \pi_{<(i,j)}$ into this cell.
- Set $\xi_\lambda(\pi) = M'$.

See also:

sulzgruber_correspondence() for the Sulzgruber correspondence as a standalone function.

pak_correspondence() for the inverse map.

EXAMPLES:

```
sage: a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
sage: A = a.sulzgruber_correspondence(); A
[[0, 1, 4], [1, 5, 5], [3, 6]]
sage: A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)

sage: a = Tableau([[1, 3], [0, 1]])
sage: a.sulzgruber_correspondence()
[[0, 4], [1, 5]]
```

symmetric_group_action_on_entries(*w*)

Return the tableau obtained form this tableau by acting by the permutation `w`.

Let T be a standard tableau of size n, then the action of $w \in S_n$ is defined by permuting the entries of T (recall they are $1, 2, \ldots, n$). In particular, suppose the entry at cell (i, j) is a, then the entry becomes $w(a)$. In general, the resulting tableau wT may *not* be standard.

Note: This is different than *symmetric_group_action_on_values()* which is defined on semistandard tableaux and is guaranteed to return a semistandard tableau.

INPUT:

- `w` – a permutation

EXAMPLES:

```
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(␣
↪Permutation(((4,5))) )
[[1, 2, 5], [3, 4]]
sage: _.category()
Category of elements of Standard tableaux
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(␣
↪Permutation(((1,2))) )
[[2, 1, 4], [3, 5]]
sage: _.category()
Category of elements of Tableaux
```

symmetric_group_action_on_values(*perm*)

Return the image of the semistandard tableau `self` under the action of the permutation `perm` using the Lascoux-Schuetzenberger action of the symmetric group S_n on the semistandard tableaux with ceiling n.

If n is a nonnegative integer, then the Lascoux-Schuetzenberger action is a group action of the symmetric group S_n on the set of semistandard Young tableaux with ceiling n (that is, with entries taken from the set $\{1, 2, \ldots, n\}$). It is defined as follows:

Let $i \in \{1, 2, \ldots, n-1\}$, and let T be a semistandard tableau with ceiling n. Let w be the reading word (*to_word()*) of T. Replace all letters i in w by closing parentheses, and all letters $i+1$ in w by opening parentheses. Whenever an opening parenthesis stands left of a closing parenthesis without there being any parentheses in between (it is allowed to have letters in-between as long as they are not parentheses), consider these two parentheses as matched with each other, and replace them back by the letters $i+1$ and i. Repeat this procedure until there are no more opening parentheses standing left of closing parentheses. Then, let a be the number of opening parentheses in the word, and b the number of closing parentheses (notice that all opening parentheses are right of all closing parentheses). Replace the first a parentheses by the letters i, and replace the remaining b parentheses by the letters $i+1$. Let w' be the resulting word. Let T' be the tableau with the same shape as T but with reading word w'. This tableau T' can be shown to be semistandard. We

define the image of T under the action of the simple transposition $s_i = (i, i+1) \in S_n$ to be this tableau T'. It can be shown that these actions of the transpositions $s_1, s_2, \ldots, s_{n-1}$ satisfy the Moore-Coxeter relations of S_n, and thus this extends to a unique action of the symmetric group S_n on the set of semistandard tableaux with ceiling n. This is the Lascoux-Schuetzenberger action.

This action of the symmetric group S_n on the set of all semistandard tableaux of given shape λ with entries in $\{1, 2, \ldots, n\}$ is the one defined in [Loth02] Theorem 5.6.3. In particular, the action of s_i is denoted by σ_i in said source. (Beware of the typo in the definition of σ_i: it should say $\sigma_i(a_i^r a_{i+1}^s) = a_i^s a_{i+1}^r$, not $\sigma_i(a_i^r a_{i+1}^s) = a_i^s a_{i+1}^s$.)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.symmetric_group_action_on_values([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2,1,3])
[[1, 2, 3, 3], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([3,1,2])
[[1, 2, 2, 2], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2,3,1])
[[1, 1, 1, 1], [2, 2], [3]]
sage: t.symmetric_group_action_on_values([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

to_Gelfand_Tsetlin_pattern()

Return the *Gelfand-Tsetlin pattern* corresponding to `self` when semistandard.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[2,3],[3]])
sage: G = T.to_Gelfand_Tsetlin_pattern(); G
[[3, 2, 1], [2, 1], [1]]
sage: G.to_tableau() == T
True
sage: T = Tableau([[1,3],[2]])
sage: T.to_Gelfand_Tsetlin_pattern()
[[2, 1, 0], [1, 1], [1]]
```

to_chain(*max_entry=None*)

Return the chain of partitions corresponding to the (semi)standard tableau `self`.

The optional keyword parameter `max_entry` can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer `n`, then the chain is constructed from the positions of the letters $1, 2, \ldots, n$ in the tableau.

EXAMPLES:

```
sage: Tableau([[1,2],[3],[4]]).to_chain()
[[], [1], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2]]).to_chain()
[[], [2], [2, 1]]
sage: Tableau([[1,1],[3]]).to_chain()
[[], [2], [2], [2, 1]]
sage: Tableau([]).to_chain()
[[]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=2)
```

(continues on next page)

(continued from previous page)

```
[[], [2], [2, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=3)
[[], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=4)
[[], [2], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: Tableau([[1,1,2],[2,3],[4,5]]).to_chain(max_entry=6)
[[], [2], [3, 1], [3, 2], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
```

to_list()

Return `self` as a list of lists (not tuples!).

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: l = t.to_list(); l
[[1, 2], [3, 4]]
sage: l[0][0] = 2
sage: t
[[1, 2], [3, 4]]
```

to_sign_matrix(*max_entry=None*)

Return the sign matrix of `self`.

A sign matrix is an $m \times n$ matrix of 0's, 1's and -1's such that the partial sums of each column is either 0 or 1 and the partial sums of each row is non-negative. [Ava2007]

INPUT:

- `max_entry` – A non-negative integer, the maximum allowable number in the tableau. Defaults to the largest entry in the tableau if not specified.

EXAMPLES:

```
sage: t = SemistandardTableau([[1,1,1,2,4],[3,3,4],[4,5],[6,6]])
sage: t.to_sign_matrix(6)                                                   #␣
↪needs sage.modules
[ 0  0  0  1  0  0]
[ 0  1  0 -1  0  0]
[ 1 -1  0  1  0  0]
[ 0  0  1 -1  1  1]
[ 0  0  0  1 -1  0]
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.to_sign_matrix(7)                                                   #␣

sage: s = Tableau([(1,0,-2,4),(3,4,5)])
sage: s.to_sign_matrix(6)
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: the entries must be non-negative integers
```

to_word()

An alias for *to_word_by_row()*.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word()
word: 325146
```

to_word_by_column()

Return the word obtained from a column reading of the tableau `self` (starting with the leftmost column, reading every column from bottom to top).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_column()
word: 3142
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_column()
word: 321546
```

to_word_by_row()

Return the word obtained from a row reading of the tableau `self` (starting with the lowermost row, reading every row from left to right).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_row()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_row()
word: 325146
```

vertical_flip()

Return the tableau obtained by vertically flipping the tableau `self`.

This only works for rectangular tableaux.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).vertical_flip()
[[3, 4], [1, 2]]
```

weight()

Return the weight of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a tableau T is the sequence $(a_1, a_2, a_3, \ldots)$, where a_k is the number of entries of T equal to k. This sequence contains only finitely many nonzero entries.

The weight of a tableau T is the same as the weight of the reading word of T, for any reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]
```

(continues on next page)

(continued from previous page)

```
sage: Tableau([]).weight()
[]

sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

class sage.combinat.tableau.**Tableau_class**(*parent*, *t*, *check=True*)

Bases: *Tableau*

This exists solely for unpickling Tableau_class objects.

class sage.combinat.tableau.**Tableaux**

Bases: UniqueRepresentation, Parent

A factory class for the various classes of tableaux.

INPUT:

- n (optional) – a non-negative integer

OUTPUT:

- If n is specified, the class of tableaux of size n. Otherwise, the class of all tableaux.

A tableau in Sage is a finite list of lists, whose lengths are weakly decreasing, or an empty list, representing the empty tableau. The entries of a tableau can be any Sage objects. Because of this, no enumeration through the set of Tableaux is possible.

EXAMPLES:

```
sage: T = Tableaux(); T
Tableaux
sage: T3 = Tableaux(3); T3
Tableaux of size 3
sage: [['a','b']] in T
True
sage: [['a','b']] in T3
False
sage: t = T3([[1,1,1]]); t
[[1, 1, 1]]
sage: t in T
True
sage: t.parent()
Tableaux of size 3
sage: T([]) # the empty tableau
[]
sage: T.category()
Category of sets
```

See also:

- *Tableau*
- *SemistandardTableaux*
- *SemistandardTableau*
- *StandardTableaux*
- *StandardTableau*

Element

alias of *Tableau*

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.tableau.**Tableaux_all**

Bases: *Tableaux*

Initializes the class of all tableaux

an_element()

Return a particular element of the class.

class sage.combinat.tableau.**Tableaux_size**(*n*)

Bases: *Tableaux*

Tableaux of a fixed size n.

an_element()

Return a particular element of the class.

sage.combinat.tableau.**from_chain**(*chain*)

Return a semistandard tableau from a chain of partitions.

EXAMPLES:

```
sage: from sage.combinat.tableau import from_chain
sage: from_chain([[], [2], [2, 1], [3, 2, 1]])
[[1, 1, 3], [2, 3], [3]]
```

sage.combinat.tableau.**from_shape_and_word**(*shape*, *w*, *convention='French'*)

Return a tableau from a shape and word.

INPUT:

- `shape` – a partition
- `w` – a word whose length equals that of the partition
- `convention` – a string which can take values `"French"` or `"English"`; the default is `"French"`

OUTPUT:

A tableau, whose shape is `shape` and whose reading word is `w`. If the `convention` is specified as `"French"`, the reading word is to be read starting from the top row in French convention (= the bottom row in English convention). If the `convention` is specified as `"English"`, the reading word is to be read starting with the top row in English convention.

EXAMPLES:

```
sage: from sage.combinat.tableau import from_shape_and_word
sage: t = Tableau([[1, 3], [2], [4]])
sage: shape = t.shape(); shape
[2, 1, 1]
sage: word = t.to_word(); word
word: 4213
sage: from_shape_and_word(shape, word)
[[1, 3], [2], [4]]
sage: word = Word(flatten(t))
```

(continues on next page)

(continued from previous page)

```
sage: from_shape_and_word(shape, word, convention="English")
[[1, 3], [2], [4]]
```

sage.combinat.tableau.**symmetric_group_action_on_values**(*word*, *perm*)

Return the image of the word `word` under the Lascoux-Schuetzenberger action of the permutation `perm`.

See *Tableau.symmetric_group_action_on_values()* for the definition of the Lascoux-Schuetzenberger action on semistandard tableaux. The transformation that the reading word of the tableau undergoes in said definition is precisely the Lascoux-Schuetzenberger action on words.

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: symmetric_group_action_on_values([1,1,1],[1,3,2])
[1, 1, 1]
sage: symmetric_group_action_on_values([1,1,1],[2,1,3])
[2, 2, 2]
sage: symmetric_group_action_on_values([1,2,1],[2,1,3])
[2, 2, 1]
sage: symmetric_group_action_on_values([2,2,2],[2,1,3])
[1, 1, 1]
sage: symmetric_group_action_on_values([2,1,2],[2,1,3])
[2, 1, 1]
sage: symmetric_group_action_on_values([2,2,3,1,1,2,2,3],[1,3,2])
[2, 3, 3, 1, 1, 2, 3, 3]
sage: symmetric_group_action_on_values([2,1,1],[2,1])
[2, 1, 2]
sage: symmetric_group_action_on_values([2,2,1],[2,1])
[1, 2, 1]
sage: symmetric_group_action_on_values([1,2,1],[2,1])
[2, 2, 1]
```

sage.combinat.tableau.**unmatched_places**(*w*, *open*, *close*)

Given a word `w` and two letters `open` and `close` to be treated as opening and closing parentheses (respectively), return a pair `(xs, ys)` that encodes the positions of the unmatched parentheses after the standard parenthesis matching procedure is applied to `w`.

More precisely, `xs` will be the list of all `i` such that `w[i]` is an unmatched closing parenthesis, while `ys` will be the list of all `i` such that `w[i]` is an unmatched opening parenthesis. Both lists returned are in increasing order.

EXAMPLES:

```
sage: from sage.combinat.tableau import unmatched_places
sage: unmatched_places([2,2,2,1,1,1],2,1)
([], [])
sage: unmatched_places([1,1,1,2,2,2],2,1)
([0, 1, 2], [3, 4, 5])
sage: unmatched_places([], 2, 1)
([], [])
sage: unmatched_places([1,2,4,6,2,1,5,3],2,1)
([0], [1])
sage: unmatched_places([2,2,1,2,4,6,2,1,5,3], 2, 1)
([], [0, 3])
sage: unmatched_places([3,1,1,1,2,1,2], 2, 1)
([1, 2, 3], [6])
```

5.1.346 Residue sequences of tableaux

A *residue sequence* for a `StandardTableau`, or `StandardTableauTuple`, of size n is an n-tuple $(i_1, i_2, \ldots, i_n)$ of elements of $\mathbf{Z}/e\mathbf{Z}$ for some positive integer $e \geq 1$. Such sequences arise in the representation theory of the symmetric group and the closely related cyclotomic Hecke algebras, and cyclotomic quiver Hecke algebras, where the residue sequences play a similar role to weights in the representations of Lie groups and Lie algebras. These Hecke algebras are semisimple when e is "large enough" and in these cases residue sequences are essentially the same as content sequences (see `sage.combinat.partition.Partition.content()`) and it is not difficult to see that residue sequences are in bijection with the set of standard tableaux. In the non-semisimple case, when e is "small", different standard tableaux can have the same residue sequence. In this case the residue sequences describe how to decompose modules into generalised eigenspaces for the Jucys-Murphy elements for these algebras.

By definition, if t is a `StandardTableau` of size n then the residue sequence of t is the n-tuple $(i_1, \ldots, i_n)$ where $i_m = c - r + e\mathbf{Z}$, if m appears in row r and column c of t. If p is prime then such sequence arise in the representation theory of the symmetric group n characteristic p. More generally, e-residue sequences arise in he representation theory of the Iwahori-Hecke algebra (see `IwahoriHeckeAlgebra`) the symmetric group with Hecke parameter at an e-th root of unity.

More generally, the e-residue sequence of a `StandardTableau` of size n and level l is the n-tuple $(i_1, \ldots, i_n)$ determined by e and a *multicharge* $\kappa = (\kappa_1, \ldots, \kappa_l)$ by setting $i_m = \kappa_k + c - r + e\mathbf{Z}$, if m appears in component k, row r and column c of t. These sequences arise in the representation theory of the cyclotomic Hecke algebras of type A, which are also known as Ariki-Koike algebras.

The residue classes are constructed from standard tableaux:

```
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)

sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,0])
3-residue sequence (0,1,2,0,0) with multicharge (0,0)
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,1])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)
```

One of the most useful functions of a `ResidueSequence` is that it can return the `StandardTableaux_residue` and `StandardTableaux_residue_shape` that contain all of the tableaux with this residue sequence. Again, these are best accessed via the standard tableaux classes:

```
sage: res = StandardTableau([[1,2],[3,4]]).residue_sequence(2)
sage: res.standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux()[:]
[[[1, 2, 4], [3]],
[[1, 2], [3, 4]],
[[1, 2], [3], [4]],
[[1, 3, 4], [2]],
[[1, 3], [2, 4]],
[[1, 3], [2], [4]]]
sage: res.standard_tableaux(shape=[4])
Standard (4)-tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux(shape=[4])[:]
[]

sage: res=StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,0])
```

(continues on next page)

(continued from previous page)

```
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,0) and multicharge (0,0)
sage: res.standard_tableaux(shape=[[1],[2,2]])[:]
[([[5]], [[1, 2], [3, 4]]), ([[4]], [[1, 2], [3, 5]])]
```

These residue sequences are particularly useful in the graded representation theory of the cyclotomic KLR algebras and the cyclotomic Hecke algebras of type~A; see [DJM1998] and [BK2009].

This module implements the following classes:

- *ResidueSequence*
- *ResidueSequences*

See also:

- *Partitions*
- *PartitionTuples*
- *StandardTableaux_residue*
- *StandardTableaux_residue_shape*
- *RowStandardTableauTuples_residue*
- *RowStandardTableauTuples_residue_shape*
- *StandardTableaux*
- *StandardTableauTuples*
- *Tableaux*
- *TableauTuples*

Todo: Strictly speaking this module implements residue sequences of type $A_e^{(1)}$. Residue sequences of other types also need to be implemented.

AUTHORS:

- Andrew Mathas (2016-07-01): Initial version

class sage.combinat.tableau_residues.**ResidueSequence**(*parent*, *residues*, *check*)

Bases: ClonableArray

A residue sequence.

The *residue sequence* of a tableau t (of partition or partition tuple shape) is the sequence $(i_1, i_2, \ldots, i_n)$ where i_k is the residue of l in t, for $k = 1, 2, \ldots, n$, where n is the size of t. Residue sequences are important in the representation theory of the cyclotomic Hecke algebras of type $G(r, 1, n)$, and of the cyclotomic quiver Hecke algebras, because they determine the eigenvalues of the Jucys-Murphy elements upon all modules. More precisely, they index and completely determine the irreducible representations of the (cyclotomic) Gelfand-Tsetlin algebras.

Rather than being called directly, residue sequences are best accessed via the standard tableaux classes *StandardTableau* and *StandardTableauTuple*.

INPUT:

Can be of the form:

- `ResidueSequence(e, res)`,

- `ResidueSequence(e, multicharge, res)`,

where `e` is a positive integer not equal to 1 and `res` is a sequence of integers (the residues).

EXAMPLES:

```
sage: res = StandardTableauTuple([[[1,3],[6]],[[2,7],[4],[5]]]).residue_
↪sequence(3,(0,5))
sage: res
3-residue sequence (0,2,1,1,0,2,0) with multicharge (0,2)
sage: res.quantum_characteristic()
3
sage: res.level()
2
sage: res.size()
7
sage: res.residues()
[0, 2, 1, 1, 0, 2, 0]
sage: res.restrict(2)
3-residue sequence (0,2) with multicharge (0,2)
sage: res.standard_tableaux([[2,1],[1],[2,1]])
Standard (2,1|1|2,1)-tableaux with 3-residue sequence (0,2,1,1,0,2,0) and␣
↪multicharge (0,2)
sage: res.standard_tableaux([[2,2],[3]]).list()
[]
sage: res.standard_tableaux([[2,2],[3]])[:]
[]
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,2,1,1,0,2,0) and multicharge (0,2)
sage: res.standard_tableaux()[:10]
[([[1, 3, 6, 7], [2, 5], [4]], []),
 ([[1, 3, 6], [2, 5], [4], [7]], []),
 ([[1, 3], [2, 5], [4, 6], [7]], []),
 ([[1, 3], [2, 5], [4], [7]], [[6]]),
 ([[1, 3], [2, 5], [4]], [[6, 7]]),
 ([[1, 3, 6, 7], [2], [4], [5]], []),
 ([[1, 3, 6], [2, 7], [4], [5]], []),
 ([[1, 3], [2, 7], [4], [5], [6]], []),
 ([[1, 3], [2, 7], [4], [5]], [[6]]),
 ([[1, 3], [2], [4], [5]], [[6, 7]])]
```

The TestSuite fails `_test_pickling` because `__getitem__` does not support slices, so we skip this.

base_ring()

Return the base ring for the residue sequence.

If the *quantum_characteristic()* of the residue sequence `self` is e then the base ring for the sequence is $\mathbf{Z}/e\mathbf{Z}$, or $\mathbf{Z}$ if $e = 0$.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).base_ring()
Ring of integers modulo 3
```

block()

Return a dictionary β that determines the block associated to the residue sequence `self`.

Two Specht modules for a cyclotomic Hecke algebra of type A belong to the same block, in this sense, if and only if the residue sequences of their standard tableaux have the same block in this sense. The blocks of these

algebras are actually indexed by positive roots in the root lattice of an affine special linear group. Instead of than constructing the root lattice, this method simply returns a dictionary β where the keys are residues i and where the value of the key i is equal to the numbers of nodes in the residue sequence `self` that are equal to i. The dictionary β corresponds to the positive root:

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

These positive roots also index the blocks of the cyclotomic KLR algebras of type A.

We return a dictionary because when the *quantum_characteristic()* is 0, the Cartan type is A_∞, in which case the simple roots are indexed by the integers, which is infinite.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,0], [0,1,2,0,1,2,0,1,2]).block()
{0: 3, 1: 3, 2: 3}
```

check()

Raise a `ValueError` if `self` is not a residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).check()
sage: ResidueSequence(3, [0,0,1], [2,0,1,1,2,2,3,3]).check()
```

level()

Return the level of the residue sequence. That is, the level of the corresponding (tuples of) standard tableaux.

The *level* of a residue sequence is the length of its *multicharge()*. This is the same as the level of the *standard_tableaux()* that belong to the residue class of tableaux determined by `self`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).level()
3
```

multicharge()

Return the multicharge for the residue sequence `self`.

The e-residue sequences are associated with a cyclotomic Hecke algebra with Hecke parameter q of *quantum_characteristic()* e and multicharge $(\kappa_1, \ldots, \kappa_l)$. This means that the cyclotomic parameters of the Hecke algebra are $q^{\kappa_1}, \ldots, q^{\kappa_l}$. Equivalently, the Hecke algebra is determined by the dominant weight

$$\sum_{r \in \mathbf{Z}/e\mathbf{Z}} \kappa_r \Lambda_r \in P^+.$$

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).multicharge()
(0, 0, 1)
```

negative()

Return the negative of the residue sequence `self`.

That is, if `self` is the residue sequence $(i_1, \ldots, i_n)$ then return $(-i_1, \ldots, -i_n)$. Taking the negative residue sequences is a shadow of tensoring with the sign representation from the cyclotomic Hecke algebras of type A.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,[0,0,1],[0,0,1,1,2,2,3,3]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)
```

quantum_characteristic()

Return the quantum characteristic of the residue sequence `self`.

The e-residue sequences are associated with a cyclotomic Hecke algebra that has a parameter q of *quantum characteristic* e. This is the smallest positive integer such that $1 + q + \cdots + q^{e-1} = 0$, or $e = 0$ if no such integer exists.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).quantum_characteristic()
3
```

residues()

Return a list of the residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).residues()
[0, 0, 1, 1, 2, 2, 0, 0]
```

restrict(m)

Return the subsequence of this sequence of length m.

The residue sequence `self` is of the form $(r_1, \ldots, r_n)$. The function returns the residue sequence $(r_1, \ldots, r_m)$, with the same *quantum_characteristic()* and *multicharge()*.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(7)
3-residue sequence (0,0,1,1,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(6)
3-residue sequence (0,0,1,1,2,2) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(4)
3-residue sequence (0,0,1,1) with multicharge (0,0,1)
```

restrict_row(*cell*, *row*)

Return a residue sequence for the tableau obtained by swapping the row in ending in $cell$ with the row that is row rows above it and which has the same length.

The residue sequence `self` is of the form $(r_1, \ldots, r_n)$. The function returns the residue sequence $(r_1, \ldots, r_m)$, with the same *quantum_characteristic()* and *multicharge()*.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,1,2,2,0,1]).restrict_row((1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (0)
sage: ResidueSequence(3, [1,0], [0,1,2,2,0,1]).restrict_row((1,1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (1,0)
```

row_standard_tableaux(*shape=None*)

Return the residue-class of row standard tableaux that have residue sequence `self`.

INPUT:

- `shape` – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the row standard tableaux with this residue sequence. If the `shape` is given then only tableaux of this shape are returned, otherwise all of the full residue-class of row standard tableaux, or row standard tableaux tuples, is returned. The residue sequence `self` specifies the *multicharge()* of the tableaux which, in turn, determines the *level()* of the tableaux in the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).row_standard_
↪tableaux([[3],[3],[3]])
Row standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
```

size()

Return the size of the residue sequence.

This is the size, or length, of the residue sequence, which is the same as the size of the *standard_tableaux()* that belong to the residue class of tableaux determined by `self`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).size()
8
```

standard_tableaux(*shape=None*)

Return the residue-class of standard tableaux that have residue sequence `self`.

INPUT:

- `shape` – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the standard tableaux with this residue sequence. If the `shape` is given then only tableaux of this shape are returned, otherwise all of the full residue-class of standard tableaux, or standard tableaux tuples, is returned. The residue sequence `self` specifies the *multicharge()* of the tableaux which, in turn, determines the *level()* of the tableaux in the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge␣
↪(0,0,0)
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).standard_tableaux([[3],
↪[3],[3]])
Standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
```

swap_residues(*i*, *j*)

Return the *new* residue sequence obtained by swapping the residues for `i` and *j*`.

INPUT:

- `i` and `j` – two integers between 1 and the length of the residue sequence

If residue sequence `self` is of the form $(r_1, \ldots, r_n)$, and $i < j$, then the residue sequence $(r_1, \ldots, r_j, \ldots, r_i, \ldots, r_m)$, with the same *quantum_characteristic()* and *multicharge()*, is returned.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: res = ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]); res
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ser = res.swap_residues(2,6); ser
3-residue sequence (0,2,1,1,2,0,0,0) with multicharge (0,0,1)
sage: res == ser
False
```

class sage.combinat.tableau_residues.**ResidueSequences**(*e*, *multicharge=(0,)*)

Bases: UniqueRepresentation, Parent

A parent class for *ResidueSequence*.

This class exists because *ResidueSequence* needs to have a parent. Apart form being a parent the only useful method that it provides is *cell_residue()*, which is a short-hand for computing the residue of a cell using the *ResidueSequence.quantum_characteristic()* and *ResidueSequence.multicharge()* for the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(e=0, multicharge=(0,1,2))
0-residue sequences with multicharge (0, 1, 2)
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=0,␣
↪multicharge=(0,1,2))
True
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=3,␣
↪multicharge=(0,1,2))
False
sage: ResidueSequences(e=0, multicharge=(0,1,2)).element_class
<class 'sage.combinat.tableau_residues.ResidueSequences_with_category.element_
↪class'>
```

Element

alias of *ResidueSequence*

an_element()

Return a particular element of `self`.

EXAMPLES:

```
sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])
```

cell_residue(**args*)

Return the residue a cell with respect to the quantum characteristic and the multicharge of the residue sequence.

INPUT:

- `r` and `c` – the row and column indices in level one
- `k`, `r` and `c` – the component, row and column indices in higher levels

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(3).cell_residue(1,1)
0
sage: ResidueSequences(3).cell_residue(2,1)
2
sage: ResidueSequences(3).cell_residue(3,1)
1
sage: ResidueSequences(3).cell_residue(3,2)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,0,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,0)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,2)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,0)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,1,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,1)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,0)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,1,0)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,1)
0
```

check_element(*element*)

Check that `element` is a residue sequence with multicharge `self.multicharge()`.

This is weak criteria in that we only require that `element` is a tuple of elements in the underlying base ring of `self`. Such a sequence is always a valid residue sequence, although there may be no tableaux with this residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]) # indirect doctest
```

(continues on next page)

(continued from previous page)

```
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,4,2,2,5,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,0,0) with multicharge (0,0,1)
```

5.1.347 TableauTuples

A *TableauTuple* is a tuple of tableaux. These objects arise naturally in representation theory of the wreath products of cyclic groups and the symmetric groups where the standard tableau tuples index bases for the ordinary irreducible representations. This generalises the well-known fact the ordinary irreducible representations of the symmetric groups have bases indexed by the standard tableaux of a given shape. More generally, *TableauTuples*, or multitableaux, appear in the representation theory of the degenerate and non-degenerate cyclotomic Hecke algebras and in the crystal theory of the integral highest weight representations of the affine special linear groups.

A *TableauTuple* is an ordered tuple $(t^{(1)}, t^{(2)}, \ldots, t^{(l)})$ of tableaux. The length of the tuple is its *level* and the tableaux $t^{(1)}, t^{(2)}, \ldots, t^{(l)}$ are the components of the *TableauTuple*.

A tableau can be thought of as the labelled diagram of a partition. Analogously, a *TableauTuple* is the labelled diagram of a *PartitionTuple*. That is, a *TableauTuple* is a tableau of *PartitionTuple* shape. As much as possible, *TableauTuples* behave in exactly the same way as *Tableaux*. There are obvious differences in that the cells of a partition are ordered pairs (r, c), where r is a row index and c a column index, whereas the cells of a *PartitionTuple* are ordered triples (k, r, c), with r and c as before and k indexes the component.

Frequently, we will call a *TableauTuple* a tableau, or a tableau of *PartitionTuple* shape. If the shape of the tableau is known this should not cause any confusion.

Warning: In sage the convention is that the (k, r, c)-th entry of a tableau tuple t is the entry in row r, column c and component k of the tableau. This is because it makes much more sense to let `t[k]` be component of the tableau. In particular, we want `t(k,r,c) == t[k][r][c]`. In the literature, the cells of a tableau tuple are usually written in the form (r, c, k), where r is the row index, c is the column index, and k is the component index.

The same convention applies to the cells of *PartitionTuples*.

Note: As with partitions and tableaux, the cells are 0-based. For example, the (lexicographically) first cell in any non-empty tableau tuple is `[0,0,0]`.

EXAMPLES:

```
sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: t = TableauTuple([ [[6,7],[8,9]],[[1,2,3],[4,5]] ]); t
([[6, 7], [8, 9]], [[1, 2, 3], [4, 5]])
sage: t.pp()
  6  7     1  2  3
  8  9     4  5
sage: t(0,0,1)
7
sage: t(1,0,1)
2
sage: t.shape()
```

(continues on next page)

(continued from previous page)

```
([2, 2], [3, 2])
sage: t.size()
9
sage: t.level()
2
sage: t.components()
[[[6, 7], [8, 9]], [[1, 2, 3], [4, 5]]]
sage: t.entries()
[6, 7, 8, 9, 1, 2, 3, 4, 5]
sage: t.parent()
Tableau tuples
sage: t.category()
Category of elements of Tableau tuples
```

One reason for implementing *TableauTuples* is to be able to consider *StandardTableauTuples*. These objects arise in many areas of algebraic combinatorics. In particular, they index bases for the Specht modules of the cyclotomic Hecke algebras of type $G(r, 1, n)$. A *StandardTableauTuple* of tableau whose entries are increasing along rows and down columns in each component and which contain the numbers $1, 2, \ldots, n$, where the shape of the *StandardTableauTuple* is a *PartitionTuple* of n.

```
sage: s = StandardTableauTuple([ [[1,2],[3]],[[4,5]]])
sage: s.category()
Category of elements of Standard tableau tuples
sage: t = TableauTuple([ [[1,2],[3]],[[4,5]]])
sage: t.is_standard(), t.is_column_strict(), t.is_row_strict()
(True, True, True)
sage: t.category()
Category of elements of Tableau tuples
sage: s == t
True
sage: s is t
False
sage: s == StandardTableauTuple(t)
True
sage: StandardTableauTuples([ [2,1],[1] ])[:]
[([[1, 2], [3]], [[4]]),
 ([[1, 3], [2]], [[4]]),
 ([[1, 2], [4]], [[3]]),
 ([[1, 3], [4]], [[2]]),
 ([[2, 3], [4]], [[1]]),
 ([[1, 4], [2]], [[3]]),
 ([[1, 4], [3]], [[2]]),
 ([[2, 4], [3]], [[1]])]
```

As tableaux (of partition shape) are in natural bijection with 1-tuples of tableaux all of the *TableauTuple* classes return an ordinary *Tableau* when given *TableauTuple* of level 1.

```
sage: TableauTuples( level=1 ) is Tableaux()
True
sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([ [[1,2,3],[4,5]] ])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([[1,2,3],[4,5]]) == Tableau([[1,2,3],[4,5]])
True
```

There is one situation where a 1-tuple of tableau is not actually a *Tableau*; tableaux generated by the *Standard-*

TableauTuples() iterators must have the correct parents, so in this one case 1-tuples of tableaux are different from *Tableaux*:

```
sage: StandardTableauTuples()[:10]                                          #␣
↪needs sage.libs.flint
[(),
 ([[1]]),
 ([], []),
 ([[1, 2]]),
 ([[1], [2]]),
 ([[1]], []),
 ([], [[1]]),
 ([], [], []),
 ([[1, 2, 3]]),
 ([[1, 3], [2]])]
```

Todo: Implement semistandard tableau tuples as defined in [DJM1998].

Much of the combinatorics implemented here is motivated by this and subsequent papers on the representation theory of these algebras.

class sage.combinat.tableau_tuple.**RowStandardTableauTuple**(*parent*, *t*, *check=True*)

Bases: *TableauTuple*

A class for row standard tableau tuples of shape a partition tuple.

A row standard tableau tuple of size n is an ordered tuple of row standard tableaux (see *RowStandardTableau*), with entries $1, 2, \ldots, n$ such that, in each component, the entries are in increasing order along each row. If the tableau in component k has shape $\lambda^{(k)}$ then $\lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)}$ is a *PartitionTuple*.

Note: The tableaux appearing in a *RowStandardTableauTuple* are row strict, but individually they are not standard tableaux because the entries in any single component of a *RowStandardTableauTuple* will typically not be in bijection with $\{1, 2, \ldots, n\}$.

INPUT:

- t – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:

- A *RowStandardTableauTuple* object constructed from t.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with *PartitionTuple*, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$. Further, the coordinates [k,r,c] in a *TableauTuple* refer to the component, row and column indices, respectively.

EXAMPLES:

```
sage: t = RowStandardTableauTuple([[[4,7],[3]],[[2,6,8],[1,5]],[[9]]]); t
([[4, 7], [3]], [[2, 6, 8], [1, 5]], [[9]])
sage: t.pp()
  4  7     2  6  8     9
  3        1  5
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp()  # pretty printing
  4  7
  3
sage: t.is_row_strict()
True
sage: t[0].is_standard()
False
sage: RowStandardTableauTuple([[],[],[]]) # An empty tableau tuple
([], [], [])
sage: RowStandardTableauTuple([[[4,5],[6]],[[1,2,3]]]) in StandardTableauTuples()
True
sage: RowStandardTableauTuple([[[5,6],[4]],[[1,2,3]]]) in StandardTableauTuples()
False
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a *RowStandardTableauTuple* from the appropriate parent object:

```
sage: RST = RowStandardTableauTuples()
sage: RST([[[4,5],[7]],[[1,2,3],[6,8]],[[9]]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

See also:

- RowTableau
- RowTableaux
- *TableauTuples*
- *TableauTuple*
- *StandardTableauTuples*
- *StandardTableauTuple*
- *RowStandardTableauTuples*

codegree(*e*, *multicharge*)

Return the Brundan-Kleshchev-Wang [BKW2011] codegree of `self`.

The *codegree* of a tableau is an integer that is defined recursively by successively stripping off the number k, for $k = n, n-1, \ldots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and which are above k in the diagram.

The codegree of the tableau `self` gives the degree of "dual" homogeneous basis element of the graded Specht module which is indexed by `self`.

INPUT:

- `e` – the *quantum characteristic*
- `multicharge` – the multicharge

OUTPUT:

The codegree of the tableau `self`, which is an integer.

EXAMPLES:

```
sage: StandardTableauTuple([[[1]], [], []]).codegree(0,(0,0,0))
0
sage: StandardTableauTuple([[],[[1]], []]).codegree(0,(0,0,0))
1
sage: StandardTableauTuple([[], [], [[1]]]).codegree(0,(0,0,0))
2
sage: StandardTableauTuple([[[1]],[[2]], []]).codegree(0,(0,0,0))
-1
sage: StandardTableauTuple([[[1]], [], [[2]]]).codegree(0,(0,0,0))
0
sage: StandardTableauTuple([[],[[1]], [[2]]]).codegree(0,(0,0,0))
1
sage: StandardTableauTuple([[[2]],[[1]], []]).codegree(0,(0,0,0))
1
sage: StandardTableauTuple([[[2]], [], [[1]]]).codegree(0,(0,0,0))
2
sage: StandardTableauTuple([[],[[2]], [[1]]]).codegree(0,(0,0,0))
3
```

degree(*e*, *multicharge*)

Return the Brundan-Kleshchev-Wang [BKW2011] degree of `self`.

The *degree* of a tableau is an integer that is defined recursively by successively stripping off the number k, for $k = n, n-1, \ldots, 1$, and at stage adding the count of the number of addable cell of the same residue minus the number of removable cells of them same residue as k and that are below k in the diagram.

Note that even though this degree function was defined by Brundan-Kleshchev-Wang [BKW2011] the underlying combinatorics is much older, going back at least to Misra and Miwa.

The degrees of the tableau T gives the degree of the homogeneous basis element of the graded Specht module which is indexed by T.

INPUT:

- `e` – the *quantum characteristic* `e`
- `multicharge` – (default: `[0]`) the multicharge

OUTPUT:

The degree of the tableau `self`, which is an integer.

EXAMPLES:

```
sage: StandardTableauTuple([[[1]], [], []]).degree(0,(0,0,0))
2
sage: StandardTableauTuple([[],[[1]], []]).degree(0,(0,0,0))
1
sage: StandardTableauTuple([[], [], [[1]]]).degree(0,(0,0,0))
0
sage: StandardTableauTuple([[[1]],[[2]], []]).degree(0,(0,0,0))
3
sage: StandardTableauTuple([[[1]], [], [[2]]]).degree(0,(0,0,0))
2
sage: StandardTableauTuple([[],[[1]], [[2]]]).degree(0,(0,0,0))
```

(continues on next page)

(continued from previous page)

```
1
sage: StandardTableauTuple([[[2]],[[1]], []]).degree(0,(0,0,0))
1
sage: StandardTableauTuple([[[2]], [], [[1]]]).degree(0,(0,0,0))
0
sage: StandardTableauTuple([[],[[2]], [[1]]]).degree(0,(0,0,0))
-1
```

inverse(*k*)

Return the cell containing `k` in the tableau tuple `self`.

EXAMPLES:

```
sage: RowStandardTableauTuple([[[3,4],[1,2]],[[5,6,7],[8]],[[9,10],[11],
↪[12]]]).inverse(1)
(0, 1, 0)
sage: RowStandardTableauTuple([[[3,4],[1,2]],[[5,6,7],[8]],[[9,10],[11],
↪[12]]]).inverse(2)
(0, 1, 1)
sage: RowStandardTableauTuple([[[3,4],[1,2]],[[5,6,7],[8]],[[9,10],[11],
↪[12]]]).inverse(3)
(0, 0, 0)
sage: RowStandardTableauTuple([[[3,4],[1,2]],[[5,6,7],[8]],[[9,10],[11],
↪[12]]]).inverse(4)
(0, 0, 1)
sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).
↪inverse(1)
(0, 0, 0)
sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).
↪inverse(2)
(0, 0, 1)
sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).
↪inverse(3)
(0, 1, 0)
sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).
↪inverse(12)
(2, 2, 0)
```

residue_sequence(*e*, *multicharge*)

Return the *sage.combinat.tableau_residues.ResidueSequence* of `self`.

INPUT:

- `e` – integer in $\{0, 2, 3, 4, 5, \ldots\}$
- `multicharge` – a sequence of integers of length equal to the level/length of `self`

OUTPUT:

The *residue sequence* of the tableau.

EXAMPLES:

```
sage: RowStandardTableauTuple([[[5]],[[3,4],[1,2]]]).residue_sequence(3,[0,0])
3-residue sequence (2,0,0,1,0) with multicharge (0,0)
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,1])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples**

Bases: *TableauTuples*

A factory class for the various classes of tuples of row standard tableau.

INPUT:

There are three optional arguments:

- `level` – the *level()* of the tuples of tableaux
- `size` – the *size()* of the tuples of tableaux
- `shape` – a list or a partition tuple specifying the *shape()* of the row standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the *level()* and the second the *size()* of the tableau tuples.

OUTPUT:

The appropriate subclass of *RowStandardTableauTuples*.

A tuple of row standard tableau is a tableau whose entries are positive integers which increase from left to right along the rows in each component. The entries do NOT need to increase from left to right along the components.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with *PartitionTuple*, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$.

EXAMPLES:

```
sage: tabs = RowStandardTableauTuples([[2],[1,1]]); tabs
Row standard tableau tuples of shape ([2], [1, 1])
sage: tabs.cardinality()
12
sage: tabs[:]                                                                 #␣
↪needs sage.graphs sage.rings.finite_rings
[([[3, 4]], [[2], [1]]),
 ([[2, 4]], [[3], [1]]),
 ([[1, 4]], [[3], [2]]),
 ([[1, 2]], [[4], [3]]),
 ([[1, 3]], [[4], [2]]),
 ([[2, 3]], [[4], [1]]),
 ([[1, 4]], [[2], [3]]),
 ([[1, 3]], [[2], [4]]),
 ([[1, 2]], [[3], [4]]),
 ([[2, 3]], [[1], [4]]),
 ([[2, 4]], [[1], [3]]),
 ([[3, 4]], [[1], [2]])]

sage: tabs = RowStandardTableauTuples(level=3); tabs
Row standard tableau tuples of level 3
sage: tabs[100]                                                               #␣
↪needs sage.libs.flint
([], [], [[2, 3], [1]])

sage: RowStandardTableauTuples()[0]                                           #␣
↪needs sage.libs.flint
([])
```

See also:

- *TableauTuples*
- *Tableau*
- *RowStandardTableau*
- *RowStandardTableauTuples*

Element

alias of *RowStandardTableauTuple*

level_one_parent_class

alias of *RowStandardTableaux_all*

shape()

Return the shape of the set of *RowStandardTableauTuples*, or `None` if it is not defined.

EXAMPLES:

```
sage: tabs=RowStandardTableauTuples(shape=[[5,2],[3,2],[],[1,1,1],[3]]); tabs
Row standard tableau tuples of shape ([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: tabs.shape()
([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: RowStandardTableauTuples().shape() is None
True
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_all**

Bases: *RowStandardTableauTuples*, DisjointUnionEnumeratedSets

Default class of all *RowStandardTableauTuples* with an arbitrary *level()* and *size()*.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableauTuples().an_element()
([[4, 5, 6, 7]], [[2, 3]], [[1]])
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_level**(*level*)

Bases: *RowStandardTableauTuples*, DisjointUnionEnumeratedSets

Class of all *RowStandardTableauTuples* with a fixed `level` and arbitrary `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableauTuples(2).an_element()
([[1]], [[2, 3]])
sage: RowStandardTableauTuples(3).an_element()
([[1]], [[2, 3]], [[4, 5, 6, 7]])
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_level_size**(*level*, *size*)

Bases: *RowStandardTableauTuples*, DisjointUnionEnumeratedSets

Class of all *RowStandardTableauTuples* with a fixed `level` and a fixed `size`.

an_element()

Return a particular element of `self`.

EXAMPLES:

```
sage: RowStandardTableauTuples(5, size=2).an_element()                    #␣
↪needs sage.libs.flint
([], [], [], [], [[1], [2]])
sage: RowStandardTableauTuples(2, size=4).an_element()                    #␣
↪needs sage.libs.flint
([[1]], [[2, 3], [4]])
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_residue**(*residue*)

Bases: *RowStandardTableauTuples*

Class of all row standard tableau tuples with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

Note: This class is not intended to be called directly, but rather, it is accessed through the row standard tableaux.

EXAMPLES:

```
sage: RowStandardTableau([[3,4,5],[1,2]]).residue_sequence(2).row_standard_
↪tableaux()
Row standard tableaux with 2-residue sequence (1,0,0,1,0) and multicharge (0)
sage: RowStandardTableau([[3,4,5],[1,2]]).residue_sequence(3).row_standard_
↪tableaux()
Row standard tableaux with 3-residue sequence (2,0,0,1,2) and multicharge (0)
sage: RowStandardTableauTuple([[[5,6],[7]],[[1,2,3],[4]]]).residue_sequence(2,(0,
↪0)).row_standard_tableaux()
Row standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,
↪0)
sage: RowStandardTableauTuple([[[5,6],[7]],[[1,2,3],[4]]]).residue_sequence(3,(0,
↪1)).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,
↪1)
```

an_element()

Return a particular element of `self`.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3).row_standard_
↪tableaux().an_element()
[[2, 3], [1]]
sage: StandardTableau([[1,3],[2]]).residue_sequence(3).row_standard_
↪tableaux().an_element()
[[1, 3], [2]]
sage: RowStandardTableauTuple([[[4]],[[2,3],[1]]]).residue_sequence(3,(0,1)).
↪row_standard_tableaux().an_element()                                     #␣
↪needs sage.libs.flint
sage: StandardTableauTuple([[[4]],[[1,3],[2]]]).residue_sequence(3,(0,1)).row_
↪standard_tableaux().an_element()                                         #␣
↪needs sage.libs.flint
([[4], [3], [1], [2]], [])
```

level()

Return the level of `self`.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().level()
2
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().level()
2
sage: RowStandardTableauTuple([[[4]],[[2,3],[1]]]).residue_sequence(3,(0,1)).
↪row_standard_tableaux().level()
2
sage: StandardTableauTuple([[[4]],[[1,3],[2]]]).residue_sequence(3,(0,1)).row_
↪standard_tableaux().level()
2
```

multicharge()

Return the multicharge of `self`.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().multicharge()
(0, 1)
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().multicharge()
(0, 1)
sage: RowStandardTableauTuple([[[4]],[[2,3],[1]]]).residue_sequence(3,(0,1)).
↪row_standard_tableaux().multicharge()
(0, 1)
sage: StandardTableauTuple([[[4]],[[1,3],[2]]]).residue_sequence(3,(0,1)).row_
↪standard_tableaux().multicharge()
(0, 1)
```

quantum_characteristic()

Return the quantum characteristic of `self`.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().quantum_characteristic()
3
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().quantum_characteristic()
3
sage: RowStandardTableauTuple([[[4]],[[2,3],[1]]]).residue_sequence(3,(0,1)).
↪row_standard_tableaux().quantum_characteristic()
3
sage: StandardTableauTuple([[[4]],[[1,3],[2]]]).residue_sequence(3,(0,1)).row_
↪standard_tableaux().quantum_characteristic()
3
```

residue_sequence()

Return the residue sequence of `self`.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().residue_sequence()
3-residue sequence (2,0,1) with multicharge (0,1)
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().residue_sequence()
3-residue sequence (0,1,2) with multicharge (0,1)
sage: RowStandardTableauTuple([[[4]],[[2,3],[1]]]).residue_sequence(3,(0,1)).
↪row_standard_tableaux().residue_sequence()
3-residue sequence (0,1,2,0) with multicharge (0,1)
sage: StandardTableauTuple([[[4]],[[1,3],[2]]]).residue_sequence(3,(0,1)).row_
↪standard_tableaux().residue_sequence()
3-residue sequence (1,0,2,0) with multicharge (0,1)
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().size()
3
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_
↪tableaux().size()
3
sage: RowStandardTableauTuple([[[4]],[[2,3],[1]]]).residue_sequence(3,(0,1)).
↪row_standard_tableaux().size()
4
sage: StandardTableauTuple([[[4]],[[1,3],[2]]]).residue_sequence(3,(0,1)).row_
↪standard_tableaux().size()
4
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_residue_shape**(*residue*, *shape*)

Bases: *RowStandardTableauTuples_residue*

All row standard tableau tuples with a fixed residue and shape.

INPUT:

- `shape` – the shape of the partitions or partition tuples
- `residue` – the residue sequence of the label

EXAMPLES:

```
sage: res = RowStandardTableauTuple([[[3,6],[1]],[[5,7],[4],[2]]]).residue_
↪sequence(3,(0,0))
sage: tabs = res.row_standard_tableaux([[2,1],[2,1,1]]); tabs
Row standard (2,1|2,1^2)-tableaux with 3-residue sequence (2,1,0,2,0,1,1) and␣
↪multicharge (0,0)
sage: tabs.shape()
([2, 1], [2, 1, 1])
sage: tabs.level()
2
sage: tabs[:6]
[([[5, 7], [4]], [[3, 6], [1], [2]]),
 ([[5, 7], [1]], [[3, 6], [4], [2]]),
 ([[3, 7], [4]], [[5, 6], [1], [2]]),
 ([[3, 7], [1]], [[5, 6], [4], [2]]),
```

(continues on next page)

(continued from previous page)

```
 ([[5, 6], [4]], [[3, 7], [1], [2]]),
 ([[5, 6], [1]], [[3, 7], [4], [2]])]
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_shape**(*shape*)

Bases: *RowStandardTableauTuples*

Class of all *RowStandardTableauTuples* of a fixed shape.

an_element()

Return a particular element of `self`.

EXAMPLES:

```
sage: RowStandardTableauTuples([[2],[2,1]]).an_element()                    #␣
↪needs sage.graphs
([[4, 5]], [[1, 3], [2]])
sage: RowStandardTableauTuples([[10],[],[]]).an_element()                   #␣
↪needs sage.graphs
([[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]], [], [])
```

cardinality()

Return the number of row standard tableau tuples of with the same shape as the partition tuple `self`.

This is just the index of the corresponding Young subgroup in the full symmetric group.

EXAMPLES:

```
sage: RowStandardTableauTuples([[3,2,1],[]]).cardinality()
60
sage: RowStandardTableauTuples([[1],[1],[1]]).cardinality()
6
sage: RowStandardTableauTuples([[2,1],[1],[1]]).cardinality()
60
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_size**(*size*)

Bases: *RowStandardTableauTuples*, DisjointUnionEnumeratedSets

Class of all *RowStandardTableauTuples* with an arbitrary `level` and a fixed `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableauTuples(size=2).an_element()
([[1]], [[2]], [], [])
sage: RowStandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [], [])
```

class sage.combinat.tableau_tuple.**StandardTableauTuple**(*parent*, *t*, *check=True*)

Bases: *RowStandardTableauTuple*

A class to model a standard tableau of shape a partition tuple. This is a tuple of standard tableau with entries $1, 2, \ldots, n$, where n is the size of the underlying partition tuple, such that the entries increase along rows and down columns in each component of the tuple.

sage: s = StandardTableauTuple([[1,2,3],[4,5]]) sage: t = StandardTableauTuple([[1,2],[3,5],[4]]) sage: s.dominates(t) True sage: t.dominates(s) False sage: StandardTableauTuple([[1,2,3],[4,5]]) in RowStandardTableauTuples() True

The tableaux appearing in a *StandardTableauTuple* are both row and column strict, but individually they are not standard tableaux because the entries in any single component of a *StandardTableauTuple* will typically not be in bijection with $\{1, 2, \ldots, n\}$.

INPUT:

- `t` – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:

- A *StandardTableauTuple* object constructed from `t`.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with *PartitionTuple*, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$. Further, the coordinates `[k,r,c]` in a *TableauTuple* refer to the component, row and column indices, respectively.

EXAMPLES:

```
sage: t = TableauTuple([ [[1,3,4],[7,9]], [[2,8,11],[6]], [[5,10]] ])
sage: t
([[1, 3, 4], [7, 9]], [[2, 8, 11], [6]], [[5, 10]])
sage: t[0][0][0]
1
sage: t[1][1][0]
6
sage: t[2][0][0]
5
sage: t[2][0][1]
10

sage: t = StandardTableauTuple([[[4,5],[7]],[[1,2,3],[6,8]],[[9]]]); t
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
sage: t.pp()
  4  5     1  2  3     9
  7        6  8
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp()  # pretty printing
  4  5
  7
sage: t.is_standard()
True
sage: t[0].is_standard()
False
sage: StandardTableauTuple([[],[],[]]) # An empty tableau tuple
([], [], [])
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a *StandardTableauTuple* from the appropriate parent object:

```
sage: STT = StandardTableauTuples()
sage: STT([[[4,5],[7]],[[1,2,3],[6,8]],[[9]]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

See also:

- *Tableau*

- *Tableaux*
- *TableauTuples*
- *TableauTuple*
- *StandardTableauTuples*

dominates(*t*)

Return `True` if the tableau (tuple) `self` dominates the tableau `t`. The two tableaux do not need to be of the same shape.

EXAMPLES:

```
sage: s = StandardTableauTuple([[1,2,3],[4,5]])
sage: t = StandardTableauTuple([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
```

restrict(*m=None*)

Return the restriction of the standard tableau `self` to `m`, which defaults to one less than the current *size()*.

EXAMPLES:

```
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(6)
([[5]], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(5)
([[5]], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(4)
([], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(3)
([], [[1, 2], [3]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(2)
([], [[1, 2]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(1)
([], [[1]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(0)
([], [])
```

Where possible the restricted tableau belongs to the same category as the tableau `self`:

```
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples([[1],[2,2]])([[[5]],[[1,2],[3,4]]]).restrict(3).
↪category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples(level=2)([[[5]],[[1,2],[3,4]]]).restrict(3).
↪category()
Category of elements of Standard tableau tuples of level 2
```

to_chain()

Return the chain of partitions corresponding to the standard tableau tuple `self`.

EXAMPLES:

```
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).to_chain()
[([], []),
  ([], [1]),
  ([], [2]),
  ([], [2, 1]),
  ([], [2, 2]),
  ([1], [2, 2])]
```

class sage.combinat.tableau_tuple.**StandardTableauTuples**

Bases: *RowStandardTableauTuples*

A factory class for the various classes of tuples of standard tableau.

INPUT:

There are three optional arguments:

- `level` – the *level()* of the tuples of tableaux
- `size` – the *size()* of the tuples of tableaux
- `shape` – a list or a partition tuple specifying the *shape()* of the standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the *level()* and the second the *size()* of the tableau tuples.

OUTPUT:

The appropriate subclass of *StandardTableauTuples*.

A tuple of standard tableau is a tableau whose entries are positive integers which increase from left to right along the rows, and from top to bottom down the columns, in each component. The entries do NOT need to increase from left to right along the components.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with *PartitionTuple*, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$.

EXAMPLES:

```
sage: tabs=StandardTableauTuples([[3],[2,2]]); tabs
Standard tableau tuples of shape ([3], [2, 2])
sage: tabs.cardinality()
70
sage: tabs[10:16]
[([[1, 2, 3]], [[4, 6], [5, 7]]),
 ([[1, 2, 4]], [[3, 6], [5, 7]]),
 ([[1, 3, 4]], [[2, 6], [5, 7]]),
 ([[2, 3, 4]], [[1, 6], [5, 7]]),
 ([[1, 2, 5]], [[3, 6], [4, 7]]),
 ([[1, 3, 5]], [[2, 6], [4, 7]])]

sage: tabs=StandardTableauTuples(level=3); tabs
Standard tableau tuples of level 3
sage: tabs[100]                                                             #␣
↪needs sage.libs.flint
([[1, 2], [3]], [], [[4]])

sage: StandardTableauTuples()[0]                                            #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.libs.flint
()
```

See also:

- *TableauTuples*
- *Tableau*
- *StandardTableau*
- *StandardTableauTuples*

Element

alias of *StandardTableauTuple*

level_one_parent_class

alias of *StandardTableaux_all*

shape()

Return the shape of the set of *StandardTableauTuples*, or `None` if it is not defined.

EXAMPLES:

```
sage: tabs=StandardTableauTuples(shape=[[5,2],[3,2],[],[1,1,1],[3]]); tabs
Standard tableau tuples of shape ([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: tabs.shape()
([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: StandardTableauTuples().shape() is None
True
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_all**

Bases: *StandardTableauTuples*, DisjointUnionEnumeratedSets

Default class of all *StandardTableauTuples* with an arbitrary *level()* and *size()*.

class sage.combinat.tableau_tuple.**StandardTableauTuples_level**(*level*)

Bases: *StandardTableauTuples*, DisjointUnionEnumeratedSets

Class of all *StandardTableauTuples* with a fixed `level` and arbitrary `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(size=2).an_element()
([[1]], [[2]], [], [])
sage: StandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [], [])
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_level_size**(*level*, *size*)

Bases: *StandardTableauTuples*, DisjointUnionEnumeratedSets

Class of all *StandardTableauTuples* with a fixed `level` and a fixed `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(5, size=2).an_element()                    #␣
↪needs sage.libs.flint
([], [], [], [], [[1], [2]])
sage: StandardTableauTuples(2, size=4).an_element()                    #␣
↪needs sage.libs.flint
([[1]], [[2, 3], [4]])
```

cardinality()

Return the number of elements in this set of tableaux.

EXAMPLES:

```
sage: StandardTableauTuples(3,2).cardinality()                         #␣
↪needs sage.libs.flint
12
sage: StandardTableauTuples(4,6).cardinality()                         #␣
↪needs sage.libs.flint
31936
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_shape**(*shape*)

Bases: *StandardTableauTuples*

Class of all *StandardTableauTuples* of a fixed shape.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,1]]).an_element()
([[2, 4]], [[1, 3], [5]])
sage: StandardTableauTuples([[10],[],[]]).an_element()
([[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]], [], [])
```

cardinality()

Return the number of standard Young tableau tuples of with the same shape as the partition tuple `self`.

Let $\mu = (\mu^{(1)}, \ldots, \mu^{(l)})$ be the `shape` of the tableaux in `self` and let $m_k = |\mu^{(k)}|$, for $1 \leq k \leq l$. Multiplying by a (unique) coset representative of the Young subgroup $S_{m_1} \times \cdots \times S_{m_l}$ inside the symmetric group S_n, we can assume that t is standard and the numbers $1, 2..., n$ are entered in order from to right along the components of the tableau. Therefore, there are

$$\binom{n}{m_1, \ldots, m_l} \prod_{k=1}^{l} |\mathrm{Std}(\mu^{(k)})|$$

standard tableau tuples of this shape, where $|\mathrm{Std}(\mu^{(k)})|$ is the number of standard tableau of shape $\mu^{(k)}$, for $1 \leq k \leq l$. This is given by the hook length formula.

EXAMPLES:

```
sage: StandardTableauTuples([[3,2,1],[]]).cardinality()
16
sage: StandardTableauTuples([[1],[1],[1]]).cardinality()
```

(continues on next page)

(continued from previous page)

```
6
sage: StandardTableauTuples([[2,1],[1],[1]]).cardinality()
40
sage: StandardTableauTuples([[3,2,1],[3,2]]).cardinality()
36960
```

last()

Return the last standard tableau tuple in `self`, with respect to the order that they are generated by the iterator.

This is just the standard tableau tuple with the numbers $1, 2, \ldots, n$, where n is *size()*, entered in order down the columns form right to left along the components.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,2]]).last().pp()
  5  6      1  3
            2  4
```

random_element()

Return a random standard tableau in `self`.

We do this by randomly selecting addable nodes to place $1, 2, \ldots, n$. Of course we could do this recursively, but it is more efficient to keep track of the (changing) list of addable nodes as we go.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,1]]).random_element()  # random
([[1, 2]], [[3, 4], [5]])
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_size**(*size*)

Bases: *StandardTableauTuples*, DisjointUnionEnumeratedSets

Class of all *StandardTableauTuples* with an arbitrary `level` and a fixed `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(size=2).an_element()
([[1]], [[2]], [], [])
sage: StandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [], [])
```

class sage.combinat.tableau_tuple.**StandardTableaux_residue**(*residue*)

Bases: *StandardTableauTuples*

Class of all standard tableau tuples with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

Note: This class is not intended to be called directly, but rather, it is accessed through the standard tableaux.

EXAMPLES:

```
sage: StandardTableau([[1,2,3],[4,5]]).residue_sequence(2).standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,0,1,0) and multicharge (0)
sage: StandardTableau([[1,2,3],[4,5]]).residue_sequence(3).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,2,0) and multicharge (0)
sage: StandardTableauTuple([[[5,6],[7]],[[1,2,3],[4]]]).residue_sequence(2,(0,0)).
↪standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,0)
sage: StandardTableauTuple([[[5,6],[7]],[[1,2,3],[4]]]).residue_sequence(3,(0,1)).
↪standard_tableaux()
Standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,1)
```

class sage.combinat.tableau_tuple.**StandardTableaux_residue_shape**(*residue*, *shape*)

Bases: *StandardTableaux_residue*

All standard tableau tuples with a fixed residue and shape.

INPUT:

- `shape` – the shape of the partitions or partition tuples
- `residue` – the residue sequence of the label

EXAMPLES:

```
sage: res = StandardTableauTuple([[[1,3],[6]],[[2,7],[4],[5]]]).residue_
↪sequence(3,(0,0))
sage: tabs = res.standard_tableaux([[2,1],[2,1,1]]); tabs
Standard (2,1|2,1^2)-tableaux with 3-residue sequence (0,0,1,2,1,2,1) and␣
↪multicharge (0,0)
sage: tabs.shape()
([2, 1], [2, 1, 1])
sage: tabs.level()
2
sage: tabs[:6]
[([[2, 7], [6]], [[1, 3], [4], [5]]),
 ([[1, 7], [6]], [[2, 3], [4], [5]]),
 ([[2, 3], [6]], [[1, 7], [4], [5]]),
 ([[1, 3], [6]], [[2, 7], [4], [5]]),
 ([[2, 5], [6]], [[1, 3], [4], [7]]),
 ([[1, 5], [6]], [[2, 3], [4], [7]])]
```

an_element()

Return a particular element of `self`.

EXAMPLES:

```
sage: T = StandardTableau([[1,3],[2]]).residue_sequence(3).standard_
↪tableaux([2,1])
sage: T.an_element()
[[1, 3], [2]]
```

class sage.combinat.tableau_tuple.**TableauTuple**(*parent*, *t*, *check=True*)

Bases: *CombinatorialElement*

A class to model a tuple of tableaux.

INPUT:

- `t` – a list or tuple of *Tableau*, a list or tuple of lists of lists

OUTPUT:

- The Tableau tuple object constructed from `t`.

A *TableauTuple* is a tuple of tableau of shape a *PartitionTuple*. These combinatorial objects are useful is several areas of algebraic combinatorics. In particular, they are important in:

- the representation theory of the complex reflection groups of type $G(l, 1, n)$ and the representation theory of the associated (degenerate and non-degenerate) Hecke algebras. See, for example, [DJM1998]
- the crystal theory of (quantum) affine special linear groups and its integral highest weight modules and their canonical bases. See, for example, [BK2009].

These apparently different and unrelated contexts are, in fact, intimately related as in characteristic zero the cyclotomic Hecke algebras categorify the canonical bases of the integral highest weight modules of the quantum affine special linear groups.

The *level()* of a tableau tuple is the length of the tuples. This corresponds to the level of the corresponding highest weight module.

In sage a *TableauTuple* looks and behaves like a real tuple of (level 1) *Tableaux*. Many of the operations which are defined on *Tableau* extend to *TableauTuples*. Tableau tuples of level 1 are just ordinary *Tableau*.

In sage, the entries of *Tableaux* can be very general, including arbitrarily nested lists, so some lists can be interpreted either as a tuple of tableaux or simply as tableaux. If it is possible to interpret the input to *TableauTuple* as a tuple of tableaux then *TableauTuple* returns the corresponding tuple. Given a 1-tuple of tableaux the tableau itself is returned.

EXAMPLES:

```
sage: t = TableauTuple([ [[6,9,10],[11]], [[1,2,3],[4,5]], [[7],[8]] ]); t
([[6, 9, 10], [11]], [[1, 2, 3], [4, 5]], [[7], [8]])
sage: t.level()
3
sage: t.size()
11
sage: t.shape()
([3, 1], [3, 2], [1, 1])
sage: t.is_standard()
True
sage: t.pp() # pretty printing
 6  9 10     1  2  3     7
11           4  5        8
sage: t.category()
Category of elements of Tableau tuples
sage: t.parent()
Tableau tuples

sage: s = TableauTuple([ [['a','c','b'],['d','e']],[[(2,1)]]]); s
([['a', 'c', 'b'], ['d', 'e']], [[(2, 1)]])
sage: s.shape()
([3, 2], [1])
sage: s.size()
6

sage: TableauTuple([[],[],[]])  # The empty 3-tuple of tableaux
([], [], [])

sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
```

(continues on next page)

(continued from previous page)

```
sage: TableauTuple([[1,2,3],[4,5]]) == Tableau([[1,2,3],[4,5]])
True
```

- *TableauTuples*
- *Tableau*
- *Tableaux*

Element

alias of *Tableau*

add_entry(*cell*, *m*)

Set the entry in `cell` equal to `m`. If the cell does not exist then extend the tableau, otherwise just replace the entry.

EXAMPLES:

```
sage: s = StandardTableauTuple([ [[3,4,7],[6,8]], [[9,13],[12]], [[1,5],[2,
↪11],[10]] ]); s.pp()
  3  4  7     9 13     1  5
  6  8       12        2 11
                      10
sage: t = s.add_entry( (0,0,3),14); t.pp(); t.category()
  3  4  7 14     9 13     1  5
  6  8          12        2 11
                         10
Category of elements of Standard tableau tuples
sage: t = s.add_entry( (0,0,3),15); t.pp(); t.category()
  3  4  7 15     9 13     1  5
  6  8          12        2 11
                         10
Category of elements of Tableau tuples
sage: t = s.add_entry( (1,1,1),14); t.pp(); t.category()
  3  4  7     9 13     1  5
  6  8       12 14     2 11
                      10
Category of elements of Standard tableau tuples
sage: t = s.add_entry( (2,1,1),14); t.pp(); t.category()
  3  4  7     9 13     1  5
  6  8       12        2 14
                      10
Category of elements of Tableau tuples
sage: t = s.add_entry( (2,1,2),14); t.pp(); t.category()
Traceback (most recent call last):
...
IndexError: (2, 1, 2) is not an addable cell of the tableau
```

cells_containing(*m*)

Return the list of cells in which the letter `m` appears in the tableau `self`.

The list is ordered with cells appearing from left to right.

EXAMPLES:

```
sage: t = TableauTuple([[[4,5]],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]])
sage: t.cells_containing(4)
[(0, 0, 0),
  (1, 2, 0),
  (1, 1, 1),
  (1, 1, 2),
  (1, 0, 3),
  (2, 1, 1),
  (2, 0, 2)]
sage: t.cells_containing(6)
[]
```

charge()

Return the charge of the reading word of `self`.

See *charge()* for more information.

EXAMPLES:

```
sage: TableauTuple([[[4,5]],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]]).charge()
4
```

cocharge()

Return the cocharge of the reading word of `self`.

See *cocharge()* for more information.

EXAMPLES:

```
sage: TableauTuple([[[4,5]],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]]).charge()
4
```

column_stabilizer()

Return the `PermutationGroup` corresponding to `self`. That is, return subgroup of the symmetric group of degree *size()* which is the column stabilizer of `self`.

EXAMPLES:

```
sage: # needs sage.groups
sage: t = TableauTuple([[[1,2,3],[4,5]],[[6,7]],[[8],[9]]])
sage: cs = t.column_stabilizer()
sage: cs.order()
8
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

components()

Return a list of the components of tableau tuple `self`.

The *components* are the individual *Tableau* which are contained in the tuple `self`.

For compatibility with *TableauTuples* of *level()* 1, *components()* should be used to iterate over the components of *TableauTuples*.

EXAMPLES:

```
sage: for t in TableauTuple([[1,2,3],[4,5]]).components(): t.pp()
  1  2  3
  4  5
sage: for t in TableauTuple([ [[1,2,3],[4,5]], [[6,7],[8,9]] ]).components():␣
↪t.pp()
  1  2  3
  4  5
  6  7
  8  9
```

conjugate()

Return the conjugate of the tableau tuple `self`.

The conjugate tableau tuple T' is the *TableauTuple* obtained from T by reversing the order of the components and conjugating each component – that is, swapping the rows and columns of the all of *Tableau* in T (see *sage.combinat.tableau.Tableau.conjugate()*).

EXAMPLES:

```
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).
↪conjugate()
([[9, 11, 12], [10]], [[5, 8], [6], [7]], [[1, 3], [2, 4]])
```

content(k, *multicharge*)

Return the content `k` in `self`.

The content of k in a standard tableau. That is, if k appears in row r and column c of the tableau, then we return $c - r + a_k$, where the multicharge is $(a_1, a_2, \ldots, a_l)$ and l is the level of the tableau.

The multicharge determines the dominant weight

$$\Lambda = \sum_{i=1}^{l} \Lambda_{a_i}$$

of the affine special linear group. In the combinatorics, the multicharge simply offsets the contents in each component so that the cell (k, r, c) has content $a_k + c - r$.

INPUT:

- `k` – an integer in $\{1, 2, \ldots, n\}$
- `multicharge` – a sequence of integers of length l

Here l is the *level()* and n is the *size()* of `self`.

EXAMPLES:

```
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).content(3,[0,0])
-1
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).content(3,[0,1])
0
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).content(3,[0,2])
1
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).content(6,[0,2])
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: 6 must be contained in the tableaux
```

entries()

Return a sorted list of all entries of `self`, in the order obtained by reading across the rows.

EXAMPLES:

```
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).entries()
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
sage: TableauTuple([[[1,2],[3,4]],[[9,10],[11],[12]],[[5,6,7],[8]]]).entries()
[1, 2, 3, 4, 9, 10, 11, 12, 5, 6, 7, 8]
```

entry(l, r, c)

Return the entry of the cell `(l, r, c)` in `self`.

A cell is a tuple `(l, r, c)` of coordinates, where `l` is the component index, `r` is the row index, and `c` is the column index.

EXAMPLES:

```
sage: t = TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]])
sage: t.entry(1, 0, 0)
5
sage: t.entry(1, 1, 1)
Traceback (most recent call last):
...
IndexError: tuple index out of range
```

first_column_descent()

Return the first cell of `self` is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, return the cell (k, r, c) with (k, r, c) minimal such that the entry in position (k, r, c) is bigger than the entry in position $(k, r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is column strict.

OUTPUT:

The cell corresponding to the first column descent or `None` if the tableau is column strict.

EXAMPLES:

```
sage: TableauTuple([[[3,5,6],[2,4,5]],[[1,4,5],[2,3]]]).first_column_descent()
(0, 0, 0)
sage: Tableau([[[1,2,3],[4]],[[5,6,7],[8,9]]]).first_column_descent() is None
True
```

first_row_descent()

Return the first cell of `self` that is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell minimal (k, r, c) such that the entry in position (k, r, c) is bigger than the entry in position $(k, r, c+1)$. If there is no such cell then `None` is returned - in this case the tableau is row strict.

OUTPUT:

The cell corresponding to the first row descent or `None` if the tableau is row strict.

EXAMPLES:

```
sage: TableauTuple([[[5,6,7],[1,2]],[[1,3,2],[4]]]).first_row_descent()
(1, 0, 1)
sage: TableauTuple([[[1,2,3],[4]],[[6,7,8],[1,2,3]],[[1,11]]]).first_row_
↪descent() is None
True
```

is_column_strict()

Return `True` if the tableau `self` is column strict and `False` otherwise.

A tableau tuple is *column strict* if the entries in each column of each component are in increasing order, when read from top to bottom.

EXAMPLES:

```
sage: TableauTuple([[[5,7],[8]],[[1, 3], [2, 4]],[[6]]]).is_column_strict()
True
sage: TableauTuple([[[1, 2], [2, 4]],[[4,5,6],[7,8]]]).is_column_strict()
True
sage: TableauTuple([[[1]],[[2, 3], [2, 4]]]).is_column_strict()
False
sage: TableauTuple([[[1]],[[2, 2], [4,5]]]).is_column_strict()
True
sage: TableauTuple([[[1,2],[6,7]],[[4,8], [6, 9]],[]]).is_column_strict()
True
```

is_row_strict()

Return `True` if the tableau `self` is row strict and `False` otherwise.

A tableau tuple is *row strict* if the entries in each row of each component are in increasing order, when read from left to right.

EXAMPLES:

```
sage: TableauTuple([[[5,7],[8]],[[1, 3], [2, 4]],[[6]]]).is_row_strict()
True
sage: TableauTuple([[[1, 2], [2, 4]],[[4,5,6],[7,8]]]).is_row_strict()
True
sage: TableauTuple([[[1]],[[2, 3], [2, 4]]]).is_row_strict()
True
sage: TableauTuple([[[1]],[[2, 2], [4,5]]]).is_row_strict()
False
sage: TableauTuple([[[1,2],[6,7]],[[4,8], [6, 9]],[]]).is_row_strict()
True
```

is_standard()

Return `True` if the tableau `self` is a standard tableau and `False` otherwise.

A tableau tuple is *standard* if it is row standard, column standard and the entries in the tableaux are $1, 2, \ldots, n$, where n is the *size()* of the underlying partition tuple of `self`.

EXAMPLES:

```
sage: TableauTuple([[[5,7],[8]],[[1, 3], [2, 4]],[[6]]]).is_standard()
True
sage: TableauTuple([[[1, 2], [2, 4]],[[4,5,6],[7,8]]]).is_standard()
False
sage: TableauTuple([[[1]],[[2, 3], [2, 4]]]).is_standard()
False
```

(continues on next page)

(continued from previous page)

```
sage: TableauTuple([[[1]],[[2, 2], [4,5]]]).is_row_strict()
False
sage: TableauTuple([[[1,2],[6,7]],[[4,8], [6, 9]],[]]).is_standard()
False
```

level()

Return the level of the tableau `self`.

This is just the number of components in the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[7,8,9]],[],[[1,2,3],[4,5],[6]]]).level()
3
```

pp()

Pretty printing for the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([ [[1,2,3],[4,5]], [[1,2,3],[4,5]] ]).pp()
  1  2  3     1  2  3
  4  5        4  5
sage: TableauTuple([ [[1,2],[3],[4]],[],[[6,7,8],[10,11],[12],[13]]]).pp()
  1  2     -     6  7  8
  3             10 11
  4             12
                13
sage: t = TableauTuple([ [[1,2,3],[4,5],[6],[9]], [[1,2,3],[4,5,8]], [[11,12,
↪13],[14]] ])
sage: t.pp()
  1  2  3     1  2  3    11 12 13
  4  5        4  5  8    14
  6
  9
sage: TableauTuples.options(convention="french")
sage: t.pp()
  9
  6
  4  5        4  5  8    14
  1  2  3     1  2  3    11 12 13
sage: TableauTuples.options._reset()
```

reduced_column_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_column_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.

EXAMPLES:

```
sage: StandardTableauTuple([[[7,9],[8]],[[1,4,6],[2,5],[3]]]).reduced_column_
↪word()
[]
sage: StandardTableauTuple([[[7,9],[8]],[[1,3,6],[2,5],[4]]]).reduced_column_
```

(continues on next page)

(continued from previous page)

```
↪word()
[3]
sage: StandardTableauTuple([[[6,9],[8]],[[1,3,7],[2,5],[4]]]).reduced_column_
↪word()
[3, 6]
sage: StandardTableauTuple([[[6,8],[9]],[[1,3,7],[2,5],[4]]]).reduced_column_
↪word()
[3, 6, 8]
sage: StandardTableauTuple([[[5,8],[9]],[[1,3,7],[2,6],[4]]]).reduced_column_
↪word()
[3, 6, 5, 8]
```

reduced_row_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.

EXAMPLES:

```
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,6],[7,8],[9]]]).reduced_row_
↪word()
[]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,6],[7,9],[8]]]).reduced_row_
↪word()
[8]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,7],[6,9],[8]]]).reduced_row_
↪word()
[6, 8]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,8],[6,9],[7]]]).reduced_row_
↪word()
[6, 8, 7]
sage: StandardTableauTuple([[[1,2],[3]],[[4,5,9],[6,8],[7]]]).reduced_row_
↪word()
[6, 7, 8, 7]
sage: StandardTableauTuple([[[7,9],[8]],[[1,3,5],[2,6],[4]]]).reduced_row_
↪word()
[2, 3, 2, 1, 4, 3, 2, 5, 4, 3, 6, 5, 4, 3, 2, 7, 6, 5, 8, 7, 6, 5, 4]
```

residue(k, e, *multicharge*)

Return the *residue* of the integer `k` in the tableau `self`.

The *residue* of k is $c - r + a_k$ in $\mathbf{Z}/e\mathbf{Z}$, where k appears in row r and column c of the tableau and the multicharge is $(a_1, a_2, \ldots, a_l)$.

The multicharge determines the dominant weight

$$\sum_{i=1}^{l} \Lambda_{a_i}$$

for the affine special linear group. In the combinatorics, it simply offsets the contents in each component so that the cell $(k, 0, 0)$ has content a_k.

INPUT:

- `k` – an integer in $\{1, 2, \ldots, n\}$

- `e` – an integer in $\{0, 2, 3, 4, 5, \ldots\}$
- `multicharge` – a list of integers of length l

Here l is the *`level()`* and n is the *`size()`* of `self`.

OUTPUT:

The residue of `k` in a standard tableau. That is,

EXAMPLES:

```
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue(1, 3,[0,0])
0
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue(1, 3,[0,1])
1
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue(1, 3,[0,2])
2
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue(6, 3,[0,2])
Traceback (most recent call last):
...
ValueError: 6 must be contained in the tableaux
```

`restrict`(*m=None*)

Return the restriction of the standard tableau `self` to `m`.

The restriction is the subtableau of `self` whose entries are less than or equal to `m`.

By default, `m` is one less than the current size.

EXAMPLES:

```
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict()
([], [[1, 2], [3, 4]])
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(6)
([[5]], [[1, 2], [3, 4]])
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(5)
([[5]], [[1, 2], [3, 4]])
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(4)
([], [[1, 2], [3, 4]])
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(3)
([], [[1, 2], [3]])
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(2)
([], [[1, 2]])
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(1)
([], [[1]])
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(0)
([], [])
```

Where possible the restricted tableau belongs to the same category as the original tableaux:

```
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuple([[[5]],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuples(level=2)([[[5]],[[1,2],[3,4]]]).restrict(3).category()
Category of elements of Tableau tuples of level 2
```

`row_stabilizer`()

Return the `PermutationGroup` corresponding to `self`. That is, return subgroup of the symmetric group of degree *`size()`* which is the row stabilizer of `self`.

EXAMPLES:

```
sage: # needs sage.groups
sage: t = TableauTuple([[[1,2,3],[4,5]],[[6,7]],[[8],[9]]])
sage: rs = t.row_stabilizer()
sage: rs.order()
24
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs.one().domain()
[1, 2, 3, 4, 5, 6, 7, 8, 9]
```

shape()

Return the *PartitionTuple* which is the shape of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[7,8,9]],[],[[1,2,3],[4,5],[6]]]).shape()
([3], [], [3, 2, 1])
```

size()

Return the size of the tableau tuple `self`.

This is just the number of boxes, or the size, of the underlying *PartitionTuple*.

EXAMPLES:

```
sage: TableauTuple([[[7,8,9]],[],[[1,2,3],[4,5],[6]]]).size()
9
```

symmetric_group_action_on_entries(*w*)

Return the action of a permutation `w` on `self`.

Consider a standard tableau tuple $T = (t^{(1)}, t^{(2)}, \dots t^{(l)})$ of size n, then the action of $w \in S_n$ is defined by permuting the entries of T (recall they are $1, 2, \dots, n$). In particular, suppose the entry at cell (k, i, j) is a, then the entry becomes $w(a)$. In general, the resulting tableau tuple wT may *not* be standard.

INPUT:

- `w` – a permutation

EXAMPLES:

```
sage: TableauTuple([[[1,2],[4]],[[3,5]]]).symmetric_group_action_on_entries(␣
↪Permutation(((4,5))) )
([[1, 2], [5]], [[3, 4]])
sage: TableauTuple([[[1,2],[4]],[[3,5]]]).symmetric_group_action_on_entries(␣
↪Permutation(((1,2))) )
([[2, 1], [4]], [[3, 5]])
```

to_list()

Return the list representation of the tableaux tuple `self`.

EXAMPLES:

```
sage: TableauTuple([ [[1,2,3],[4,5]], [[6,7],[8,9]] ]).to_list()
[[[1, 2, 3], [4, 5]], [[6, 7], [8, 9]]]
```

to_permutation()

Return a permutation with the entries in the tableau tuple `self`.

The permutation is obtained from `self` by reading the entries of the tableau tuple in order from left to right along the rows, and then top to bottom, in each component and then left to right along the components.

EXAMPLES:

```
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).to_
↪permutation()
[12, 11, 9, 10, 8, 5, 6, 7, 3, 4, 1, 2]
```

to_word()

Return a word obtained from a row reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).to_word_
↪by_row()
word: 12,11,9,10,8,5,6,7,3,4,1,2
```

to_word_by_column()

Return the word obtained from a column reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).to_word_
↪by_column()
word: 12,11,9,10,8,5,6,7,3,1,4,2
```

to_word_by_row()

Return a word obtained from a row reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]]).to_word_
↪by_row()
word: 12,11,9,10,8,5,6,7,3,4,1,2
```

up(*n=None*)

An iterator for all the *TableauTuple* that can be obtained from `self` by adding a cell with the label `n`. If `n` is not specified then a cell with label `n` will be added to the tableau tuple, where `n-1` is the size of the tableau tuple before any cells are added.

EXAMPLES:

```
sage: list(TableauTuple([[[1,2]],[[3]]]).up())
[([[1, 2, 4]], [[3]]),
 ([[1, 2], [4]], [[3]]),
 ([[1, 2]], [[3, 4]]),
 ([[1, 2]], [[3], [4]])]
```

class sage.combinat.tableau_tuple.**TableauTuples**

Bases: UniqueRepresentation, Parent

A factory class for the various classes of tableau tuples.

INPUT:

There are three optional arguments:

- shape – determines a *PartitionTuple* which gives the shape of the *TableauTuples*
- level – the level of the tableau tuples (positive integer)
- size – the size of the tableau tuples (non-negative integer)

It is not necessary to use the keywords. If they are not specified then the first integer argument specifies the level and the second the size of the tableaux.

OUTPUT:

- The corresponding class of tableau tuples.

The entries of a tableau can be any sage object. Because of this, no enumeration of the set of *TableauTuples* is possible.

EXAMPLES:

```
sage: T3 = TableauTuples(3); T3
Tableau tuples of level 3
sage: [['a','b']] in TableauTuples()
True
sage: [['a','b']] in TableauTuples(level=3)
False
sage: t = TableauTuples(level=3)([[],[[1,1,1]],[]]); t
([], [[1, 1, 1]], [])
sage: t in T3
True
sage: t in TableauTuples()
True
sage: t in TableauTuples(size=3)
True
sage: t in TableauTuples(size=4)
False
sage: t in StandardTableauTuples()
False
sage: t.parent()
Tableau tuples of level 3
sage: t.category()
Category of elements of Tableau tuples of level 3
```

See also:

- *Tableau*
- *StandardTableau*
- *StandardTableauTuples*

Element

alias of *TableauTuple*

level()

Return the level of a tableau tuple in self, or None if different tableau tuples in self can have different sizes. The level of a tableau tuple is just the level of the underlying *PartitionTuple*.

EXAMPLES:

```
sage: TableauTuples().level() is None
True
```

(continues on next page)

(continued from previous page)

```
sage: TableauTuples(7).level()
7
```

level_one_parent_class

alias of *Tableaux_all*

list()

If the set of tableau tuples `self` is finite then this function returns the list of these tableau tuples. If the class is infinite an error is returned.

EXAMPLES:

```
sage: StandardTableauTuples([[2,1],[2]]).list()
[([[1, 2], [3]], [[4, 5]]),
 ([[1, 3], [2]], [[4, 5]]),
 ([[1, 2], [4]], [[3, 5]]),
 ([[1, 3], [4]], [[2, 5]]),
 ([[2, 3], [4]], [[1, 5]]),
 ([[1, 4], [2]], [[3, 5]]),
 ([[1, 4], [3]], [[2, 5]]),
 ([[2, 4], [3]], [[1, 5]]),
 ([[1, 2], [5]], [[3, 4]]),
 ([[1, 3], [5]], [[2, 4]]),
 ([[2, 3], [5]], [[1, 4]]),
 ([[1, 4], [5]], [[2, 3]]),
 ([[2, 4], [5]], [[1, 3]]),
 ([[3, 4], [5]], [[1, 2]]),
 ([[1, 5], [2]], [[3, 4]]),
 ([[1, 5], [3]], [[2, 4]]),
 ([[2, 5], [3]], [[1, 4]]),
 ([[1, 5], [4]], [[2, 3]]),
 ([[2, 5], [4]], [[1, 3]]),
 ([[3, 5], [4]], [[1, 2]])]
```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

size()

Return the `size` of a tableau tuple in `self`, or `None` if different tableau tuples in `self` can have different sizes. The `size` of a tableau tuple is just the size of the underlying *PartitionTuple*.

EXAMPLES:

```
sage: TableauTuples(size=14).size()
14
```

class sage.combinat.tableau_tuple.**TableauTuples_all**

Bases: *TableauTuples*

The parent class of all *TableauTuples*, with arbitrary `level` and `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])
```

class sage.combinat.tableau_tuple.**TableauTuples_level**(*level*)

Bases: *TableauTuples*

Class of all *TableauTuples* with a fixed `level` and arbitrary `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(3).an_element()
([], [], [])
sage: TableauTuples(5).an_element()
([], [], [], [], [])
sage: T = TableauTuples(0)
Traceback (most recent call last):
...
ValueError: the level must be a positive integer
```

class sage.combinat.tableau_tuple.**TableauTuples_level_size**(*level*, *size*)

Bases: *TableauTuples*

Class of all *TableauTuples* with a fixed `level` and a fixed `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(3,0).an_element()
([], [], [])
sage: TableauTuples(3,1).an_element()
([[1]], [], [])
sage: TableauTuples(3,2).an_element()
([[1, 2]], [], [])
```

class sage.combinat.tableau_tuple.**TableauTuples_size**(*size*)

Bases: *TableauTuples*

Class of all *TableauTuples* with a arbitrary `level` and fixed `size`.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(size=3).an_element()
([], [[1, 2, 3]], [])
sage: TableauTuples(size=0).an_element()
([], [], [])
```

5.1.348 Generalized Tamari lattices

These lattices depend on three parameters a, b and m, where a and b are positive integers and m is a nonnegative integer.

The elements are *Dyck paths* in the $(a \times b)$-rectangle. The order relation depends on m.

To use the provided functionality, you should import Generalized Tamari lattices by typing:

```
sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
```

Then,

```
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
```

The classical **Tamari lattices** are special cases of this construction and are also available directly using the catalogue of posets, as follows:

```
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements
```

See also:

For more detailed information see *TamariLattice()*, *GeneralizedTamariLattice()*.

sage.combinat.tamari_lattices.**DexterSemilattice**(*n*)

Return the n-th Dexter meet-semilattice.

INPUT:

- n – a nonnegative integer (the index)

OUTPUT:

a finite meet-semilattice

The elements of the semilattice are *Dyck paths* in the $(n+1 \times n)$-rectangle.

EXAMPLES:

```
sage: posets.DexterSemilattice(3)
Finite meet-semilattice containing 5 elements

sage: P = posets.DexterSemilattice(4); P
Finite meet-semilattice containing 14 elements
sage: len(P.maximal_chains())
15
sage: len(P.maximal_elements())
4
sage: P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1
```

REFERENCES:

- [Cha18]

sage.combinat.tamari_lattices.**GeneralizedTamariLattice**(*a*, *b*, *m=1*)

Return the (a, b)-Tamari lattice of parameter m.

INPUT:

- a and b – integers with $a \geq b$
- m – a nonnegative rational number such that $a \geq bm$

OUTPUT:

- a finite lattice (special case of the alt ν-Tamari lattices in [CC2023])

The elements of the lattice are *Dyck paths* in the $(a \times b)$-rectangle.

The parameter m (slope) is used only to define the covering relations. When the slope m is 0, two paths are comparable if and only if one is always above the other.

The usual Tamari lattice of index b is the special case $a = b + 1$ and $m = 1$.

Other special cases give the m-Tamari lattices studied in [BMFPR2011], or the rational Tamari lattices when a and b are coprime and m = a/b (see [PRV2017]).

EXAMPLES:

```
sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
sage: GeneralizedTamariLattice(7,5,2)
Traceback (most recent call last):
...
ValueError: the condition a>=b*m does not hold
sage: P = GeneralizedTamariLattice(5,3); P
Finite lattice containing 7 elements
sage: P = GeneralizedTamariLattice(5, 3, m=5/3); P
Finite lattice containing 7 elements
```

REFERENCES:

- [BMFPR2011]
- [PRV2017]
- [CC2023]

sage.combinat.tamari_lattices.**TamariLattice**(*n*, *m=1*)

Return the n-th Tamari lattice.

Using the slope parameter m, one can also get the m-Tamari lattices.

INPUT:

- n – a nonnegative integer (the index)
- m – an optional nonnegative integer (the slope, default to 1)

OUTPUT:

a finite lattice

In the usual case, the elements of the lattice are *Dyck paths* in the $(n + 1 \times n)$-rectangle. For a general slope m, the elements are Dyck paths in the $(mn + 1 \times n)$-rectangle.

See Tamari lattice for mathematical background.

EXAMPLES:

```
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements

sage: posets.TamariLattice(3, 2)
Finite lattice containing 12 elements
```

REFERENCES:

- [BMFPR2011]

sage.combinat.tamari_lattices.**paths_in_triangle**(*i*, *j*, *a*, *b*)

Return all Dyck paths from $(0, 0)$ to (i, j) in the $(a \times b)$-rectangle.

This means that at each step of the path, one has $ay \geq bx$.

A path is represented by a sequence of 0 and 1, where 0 is an horizontal step $(1, 0)$ and 1 is a vertical step $(0, 1)$.

INPUT:

- a and b – integers with $a \geq b$
- i and j – nonnegative integers with $1 \geq \frac{j}{b} \geq \frac{i}{a} \geq 0$

OUTPUT:

- a list of paths

EXAMPLES:

```
sage: from sage.combinat.tamari_lattices import paths_in_triangle
sage: paths_in_triangle(2,2,2,2)
[(1, 0, 1, 0), (1, 1, 0, 0)]
sage: paths_in_triangle(2,3,4,4)
[(1, 0, 1, 0, 1), (1, 1, 0, 0, 1), (1, 0, 1, 1, 0),
(1, 1, 0, 1, 0), (1, 1, 1, 0, 0)]
sage: paths_in_triangle(2,1,4,4)
Traceback (most recent call last):
...
ValueError: the endpoint is not valid
sage: paths_in_triangle(3,2,5,3)
[(1, 0, 1, 0, 0), (1, 1, 0, 0, 0)]
```

sage.combinat.tamari_lattices.**swap**(*p*, *i*, *m=1*)

Perform a covering move in the (a, b)-Tamari lattice of slope parameter m.

The letter at position i in p must be a 0, followed by at least one 1.

INPUT:

- `p` – a Dyck path in the $(a \times b)$-rectangle
- `i` – an integer between 0 and $a + b - 1$

OUTPUT:

- a Dyck path in the $(a \times b)$-rectangle

EXAMPLES:

```
sage: from sage.combinat.tamari_lattices import swap
sage: swap((1,0,1,0,0),1)
(1, 1, 0, 0, 0)
sage: swap((1,1,0,0,1,1,0,0,0),3)
```

(continues on next page)

(continued from previous page)

```
(1, 1, 0, 1, 1, 0, 0, 0, 0)
sage: swap((1,0,1,0,1,0,0,0), 1, 1)
(1, 1, 0, 0, 1, 0, 0, 0)
sage: swap((1,0,1,0,1,0,0,0), 1, 5/3)
(1, 1, 0, 1, 0, 0, 0, 0)
```

sage.combinat.tamari_lattices.**swap_dexter**(p, i)

Perform covering moves in the (a, b)-Dexter posets.

The letter at position i in p must be a 0, followed by at least one 1.

INPUT:

- p – a Dyck path in the $(a \times b)$-rectangle
- i – an integer between 0 and $a + b - 1$

OUTPUT:

- a list of Dyck paths in the $(a \times b)$-rectangle

EXAMPLES:

```
sage: from sage.combinat.tamari_lattices import swap_dexter
sage: swap_dexter((1,0,1,0,0),1)
[(1, 1, 0, 0, 0)]
sage: swap_dexter((1,1,0,0,1,1,0,0,0),3)
[(1, 1, 0, 1, 1, 0, 0, 0, 0), (1, 1, 1, 1, 0, 0, 0, 0, 0)]
sage: swap_dexter((1,1,0,1,0,0,0),2)
[]
```

5.1.349 Tiling Solver

Tiling a n-dimensional polyomino with n-dimensional polyominoes.

This module defines two classes:

- *sage.combinat.tiling.Polyomino* class, to represent polyominoes in arbitrary dimension. The goal of this class is to return all the rotated, reflected and/or translated copies of a polyomino that are contained in a certain box.
- *sage.combinat.tiling.TilingSolver* class, to solve the problem of tiling a n-dimensional polyomino with a set of n-dimensional polyominoes. One can specify if rotations and reflections are allowed or not and if pieces can be reused or not. This class convert the tiling data into rows of a matrix that are passed to the DLX solver. It also allows to compute the number of solutions.

This uses dancing links code which is in Sage. Dancing links were originally introduced by Donald Knuth in 2000 [Knuth1]. Knuth used dancing links to solve tilings of a region by 2d pentaminoes. Here we extend the method to any dimension.

In particular, the sage.games.quantumino module is based on the Tiling Solver and allows to solve the 3d Quantumino puzzle.

AUTHOR:

- Sébastien Labbé, June 2011, initial version
- Sébastien Labbé, July 2015, count solutions up to rotations
- Sébastien Labbé, April 2017, tiling a polyomino, not only a rectangular box

EXAMPLES:

2d Easy Example

Here is a 2d example. Let us try to fill the 3×2 rectangle with a 1×2 rectangle and a 2×2 square. Obviously, there are two solutions:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2])
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0, 0), (0, 1), (1, 0), (1, 1)], Color: gray,
 Polyomino: [(2, 0), (2, 1)], Color: gray]
sage: next(it)
[Polyomino: [(1, 0), (1, 1), (2, 0), (2, 1)], Color: gray,
 Polyomino: [(0, 0), (0, 1)], Color: gray]
sage: next(it)
Traceback (most recent call last):
...
StopIteration
sage: T.number_of_solutions()
2
```

Scott's pentamino problem

As mentioned in the introduction of [Knuth1], Scott's pentamino problem consists in tiling a chessboard leaving the center four squares vacant with the 12 distinct pentaminoes.

The 12 pentaminoes:

```
sage: from sage.combinat.tiling import Polyomino
sage: I = Polyomino([(0,0),(1,0),(2,0),(3,0),(4,0)], color='brown')
sage: N = Polyomino([(1,0),(1,1),(1,2),(0,2),(0,3)], color='yellow')
sage: L = Polyomino([(0,0),(1,0),(0,1),(0,2),(0,3)], color='magenta')
sage: U = Polyomino([(0,0),(1,0),(0,1),(0,2),(1,2)], color='violet')
sage: X = Polyomino([(1,0),(0,1),(1,1),(1,2),(2,1)], color='pink')
sage: W = Polyomino([(2,0),(2,1),(1,1),(1,2),(0,2)], color='green')
sage: P = Polyomino([(1,0),(2,0),(0,1),(1,1),(2,1)], color='orange')
sage: F = Polyomino([(1,0),(1,1),(0,1),(2,1),(2,2)], color='gray')
sage: Z = Polyomino([(0,0),(1,0),(1,1),(1,2),(2,2)], color='yellow')
sage: T = Polyomino([(0,0),(0,1),(1,1),(2,1),(0,2)], color='red')
sage: Y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='green')
sage: V = Polyomino([(0,0),(0,1),(0,2),(1,0),(2,0)], color='blue')
```

A 8×8 chessboard leaving the center four squares vacant:

```
sage: import itertools
sage: s = set(itertools.product(range(8), repeat=2))
sage: s.difference_update([(3,3), (3,4), (4,3), (4,4)])
sage: chessboard = Polyomino(s)
sage: len(chessboard)
60
```

This problem is represented by a matrix made of 1568 rows and 72 columns. It has 65 different solutions up to isometries:

```
sage: from sage.combinat.tiling import TilingSolver
sage: T = TilingSolver([I,N,L,U,X,W,P,F,Z,T,Y,V], box=chessboard, reflection=True)
sage: T
Tiling solver of 12 pieces into a box of size 60
Rotation allowed: True
Reflection allowed: True
Reusing pieces allowed: False
sage: len(T.rows())                # long time
1568
sage: T.number_of_solutions()      # long time
520
sage: 520 / 8
65
```

Showing one solution:

```
sage: solution = next(T.solve())                                    # long time
sage: G = sum([piece.show2d() for piece in solution], Graphics())   # long time,␣
↪needs sage.plot
sage: G.show(aspect_ratio=1, axes=False)                            # long time,␣
↪needs sage.plot
```

1d Easy Example

Here is an easy one dimensional example where we try to tile a stick of length 6 with three sticks of length 1, 2 and 3. There are six solutions:

```
sage: p = Polyomino([[0]])
sage: q = Polyomino([[0],[1]])
sage: r = Polyomino([[0],[1],[2]])
sage: T = TilingSolver([p,q,r], box=[6])
sage: len(T.rows())
15
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0)], Color: gray,
 Polyomino: [(1), (2)], Color: gray,
 Polyomino: [(3), (4), (5)], Color: gray]
sage: next(it)
[Polyomino: [(0)], Color: gray,
 Polyomino: [(1), (2), (3)], Color: gray,
 Polyomino: [(4), (5)], Color: gray]
sage: T.number_of_solutions()
6
```

2d Puzzle allowing reflections

The following is a puzzle owned by Florent Hivert:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,2),(1,3)], 'yellow'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,2)], "black"))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,3)], "gray"))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,3)],"cyan"))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1)],"red"))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,1),(1,2)],"blue"))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,1),(1,3)],"green"))
sage: L.append(Polyomino([(0,1),(0,2),(0,3),(1,0),(1,1),(1,3)],"magenta"))
sage: L.append(Polyomino([(0,1),(0,2),(0,3),(1,0),(1,1),(1,2)],"orange"))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(1,0),(1,1),(1,2)],"pink"))
```

By default, rotations are allowed and reflections are not. In this case, there are no solution for tiling a 8×8 rectangular box:

```
sage: T = TilingSolver(L, box=(8,8))
sage: T.number_of_solutions()                                   # long time (2.5s)
0
```

If reflections are allowed, there are solutions. Solve the puzzle and show one solution:

```
sage: T = TilingSolver(L, box=(8,8), reflection=True)
sage: solution = next(T.solve())                                # long time (7s)
sage: G = sum([piece.show2d() for piece in solution], Graphics())   # long time (<1s),
↪ needs sage.plot
sage: G.show(aspect_ratio=1, axes=False)                        # long time (2s),␣
↪needs sage.plot
```

Compute the number of solutions:

```
sage: T.number_of_solutions()                                   # long time (2.6s)
328
```

Create a animation of all the solutions:

```
sage: a = T.animate()                                 # not tested
sage: a                                               # not tested
Animation with 328 frames
```

3d Puzzle

The same thing done in 3d *without* allowing reflections this time:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,
↪3,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,3,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,3,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0)]))
```

(continues on next page)

(continued from previous page)

```
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,1,0),(1,2,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,1,0),(1,3,0)]))
sage: L.append(Polyomino([(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,3,0)]))
sage: L.append(Polyomino([(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(1,0,0),(1,1,0),(1,2,0)]))
```

Solve the puzzle and show one solution:

```
sage: T = TilingSolver(L, box=(8,8,1))
sage: solution = next(T.solve())                                    # long time (8s)
sage: G = sum([p.show3d(size=0.85) for p in solution], Graphics())  # long time (<1s),
↪ needs sage.plot
sage: G.show(aspect_ratio=1, viewer='tachyon')                      # long time (2s),␣
↪needs sage.plot
```

Let us compute the number of solutions:

```
sage: T.number_of_solutions()                                       # long time (3s)
328
```

Donald Knuth example : the Y pentamino

Donald Knuth [Knuth1] considered the problem of packing 45 Y pentaminoes into a 15×15 square:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)])
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: T.number_of_solutions()
10
sage: solution = next(T.solve())
sage: G = sum([p.show2d() for p in solution], Graphics())                                #␣
↪needs sage.plot
sage: G.show(aspect_ratio=1)                                        # long time (2s),␣
↪needs sage.plot
```

```
sage: T = TilingSolver([y], box=(15,15), reusable=True, reflection=True)
sage: T.number_of_solutions()                       # not tested
1696
```

Up to the symmetries of the square, there are 212 distinct solutions:

```
sage: 1696 // 8
212
```

Animation of Donald Knuth's dancing links

Animation of the solutions:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: Y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='yellow')
sage: T = TilingSolver([Y], box=(15,15), reusable=True, reflection=True)
sage: a = T.animate(stop=40); a                    # long time, optional -␣
↪imagemagick, needs sage.plot
Animation with 40 frames
```

Incremental animation of the solutions (one piece is removed/added at a time):

```
sage: a = T.animate('incremental', stop=40); a     # long time, optional -␣
↪imagemagick, needs sage.plot
Animation with 40 frames
sage: a.show(delay=50, iterations=1)               # long time, optional -␣
↪imagemagick, needs sage.plot
```

5d Easy Example

Here is a 5d example. Let us try to fill the $2 \times 2 \times 2 \times 2 \times 2$ rectangle with reusable $1 \times 1 \times 1 \times 1 \times 1$ rectangles. Obviously, there is one solution:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0,0,0,0)])
sage: T = TilingSolver([p], box=(2,2,2,2,2), reusable=True)
sage: rows = T.rows()                              # long time (3s)
sage: rows                                         # long time (fast)

REFERENCES:

class sage.combinat.tiling.**Polyomino**(*coords*, *color='gray'*, *dimension=None*)

Bases: SageObject

A polyomino in $\mathbf{Z}^d$.

The polyomino is the union of the unit square (or cube, or n-cube) centered at those coordinates. Such an object should be connected, but the code does not make this assumption.

INPUT:

- `coords` – iterable of integer coordinates in $\mathbf{Z}^d$
- `color` – string (default: `'gray'`), color for display
- `dimension` – integer (default: `None`), dimension of the space, if `None`, it is guessed from the `coords` if `coords` is non empty

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
Polyomino: [(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)], Color: blue
```

boundary()

Return the boundary of a 2d polyomino.

INPUT:

- `self` – a 2d polyomino

OUTPUT:

- list of edges (an edge is a pair of adjacent 2d coordinates)

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0), (1,0), (0,1), (1,1)])
sage: sorted(p.boundary())
[((-0.5, -0.5), (-0.5, 0.5)), ((-0.5, -0.5), (0.5, -0.5)),
 ((-0.5, 0.5), (-0.5, 1.5)), ((-0.5, 1.5), (0.5, 1.5)),
 ((0.5, -0.5), (1.5, -0.5)), ((0.5, 1.5), (1.5, 1.5)),
 ((1.5, -0.5), (1.5, 0.5)), ((1.5, 0.5), (1.5, 1.5))]
sage: len(_)
8
sage: p = Polyomino([(5,5)])
sage: sorted(p.boundary())
[((4.5, 4.5), (4.5, 5.5)), ((4.5, 4.5), (5.5, 4.5)),
 ((4.5, 5.5), (5.5, 5.5)), ((5.5, 4.5), (5.5, 5.5))]
```

bounding_box()

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink
↪')
sage: p.bounding_box()
[[0, 0, 0], [1, 2, 1]]
```

canonical()

Return the translated copy of `self` having minimal and nonnegative coordinates

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink
↪')
sage: p
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color:␣
↪deeppink
sage: p.canonical()
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color:␣
↪deeppink
```

canonical_isometric_copies(*orientation_preserving=True*, *mod_box_isometries=False*)

Return the list of image of `self` under isometries of the n-cube where the coordinates are all nonnegative and minimal.

INPUT:

- `orientation_preserving` – bool (default: `True`); if `True`, the group of isometries of the n-cube is restricted to those that preserve the orientation, i.e. of determinant 1.

- `mod_box_isometries` – bool (default: `False`), whether to quotient the group of isometries of the n-cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where are the a_i are assumed to be distinct.

OUTPUT:

set of Polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: s = p.canonical_isometric_copies()
sage: len(s)
12
```

With the non orientation-preserving:

```
sage: s = p.canonical_isometric_copies(orientation_preserving=False)
sage: len(s)
24
```

Modulo rotation by angle 180 degrees:

```
sage: s = p.canonical_isometric_copies(mod_box_isometries=True)
sage: len(s)
3
```

center()

Return the center of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(0,0,1)])
sage: p.center()
(0, 0, 1/2)
```

In 3d:

```
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink
↪')
sage: p.center()
(4/5, 4/5, 1/5)
```

In 2d:

```
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])
sage: p.center()
(3/4, 3/4)
```

color(*color=None*)

Return or change the color of the polyomino.

INPUT:

- `color` – string, RBG tuple or `None` (default: `None`), if `None`, it returns the current color

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.color()
'blue'
```

frozenset()

Return the elements of $\mathbf{Z}^d$ in the polyomino as a frozenset.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='red')
sage: p.frozenset()
frozenset({(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)})
```

intersection(*other*)

Return the intersection of `self` and `other`.

INPUT:

- `other` – a polyomino

OUTPUT:

polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: a = Polyomino([(0,0)])
sage: b = Polyomino([(0,0), (0,1), (1,1), (2,1)])
sage: a.intersection(b)
Polyomino: [(0, 0)], Color: gray
sage: a.intersection(b+(1,1))
Polyomino: [], Color: gray
```

isometric_copies(*box*, *orientation_preserving=True*, *mod_box_isometries=False*)

Return the translated and isometric images of `self` that lies in the box.

INPUT:

- `box` – Polyomino or tuple of integers (size of a box)
- `orientation_preserving` – bool (default: `True`); If `True`, the group of isometries of the n-cube is restricted to those that preserve the orientation, i.e. of determinant 1.
- `mod_box_isometries` – bool (default: `False`), whether to quotient the group of isometries of the n-cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where are the a_i are assumed to be distinct.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink
↪')
sage: L = list(p.isometric_copies(box=(5,8,2)))
sage: len(L)
360
```

```
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,2,0),(1,2,1)], color='orange')
sage: L = list(p.isometric_copies(box=(5,8,2)))
sage: len(L)
180
sage: L = list(p.isometric_copies((5,8,2), False))
sage: len(L)
360
sage: L = list(p.isometric_copies((5,8,2), mod_box_isometries=True))
sage: len(L)
45
```

```
sage: p = Polyomino([(0,0), (1,0), (0,1)])
sage: b = Polyomino([(0,0), (1,0), (2,0), (0,1), (1,1), (0,2)])
sage: sorted(p.isometric_copies(b), key=lambda p: p.sorted_list())
[Polyomino: [(0, 0), (0, 1), (1, 0)], Color: gray,
 Polyomino: [(0, 0), (0, 1), (1, 1)], Color: gray,
 Polyomino: [(0, 0), (1, 0), (1, 1)], Color: gray,
 Polyomino: [(0, 1), (0, 2), (1, 1)], Color: gray,
 Polyomino: [(0, 1), (1, 0), (1, 1)], Color: gray,
 Polyomino: [(1, 0), (1, 1), (2, 0)], Color: gray]
```

isometric_copies_intersection(*box*, *orientation_preserving=True*)

Return the set of non empty intersections of isometric images of `self` with a polyomino.

INPUT:

- `box` – Polyomino or tuple of integers (size of a box)
- `orientation_preserving` – bool (default: `True`); if `True`, the group of isometries of the n-cube is restricted to those that preserve the orientation, i.e. of determinant 1.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0)], color='deeppink')
sage: sorted(sorted(a.frozenset()) for a in p.isometric_copies_
↪intersection(box=(2,3)))
[[(0, 0)],
 [(0, 0), (0, 1)],
 [(0, 0), (1, 0)],
 [(0, 1)],
 [(0, 1), (0, 2)],
 [(0, 1), (1, 1)],
 [(0, 2)],
 [(0, 2), (1, 2)],
 [(1, 0)],
 [(1, 0), (1, 1)],
 [(1, 1)],
 [(1, 1), (1, 2)],
 [(1, 2)]]
```

neighbor_edges()

Return an iterator over the pairs of neighbor coordinates inside of the polyomino.

Two points P and Q in the polyomino are neighbor if $P - Q$ has one coordinate equal to $+1$ or -1 and zero everywhere else.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(0,0,1)])
sage: [sorted(edge) for edge in p.neighbor_edges()]
[[(0, 0, 0), (0, 0, 1)]]
```

In 3d:

```
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink
↪')
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
sage: for a in L: a
[(0, 0, 0), (1, 0, 0)]
[(1, 0, 0), (1, 1, 0)]
[(1, 1, 0), (1, 1, 1)]
[(1, 1, 0), (1, 2, 0)]
```

In 2d:

```
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
sage: for a in L: a
[(0, 0), (1, 0)]
[(1, 0), (1, 1)]
[(1, 1), (1, 2)]
```

self_surrounding(*radius*, *remove_incomplete_copies=True*, *ncpus=None*)

Return a list of isometric copies of `self` surrounding it with an annulus of given radius.

INPUT:

- `self` – a polyomino of dimension 2
- `radius` – integer
- `remove_incomplete_copies` – bool (default: `True`), whether to keep only complete copies of `self` in the output
- `ncpus` – integer (default: `None`), maximal number of subprocesses to use at the same time. If `None`, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`. If `ncpus=1`, the first solution is searched serially.

OUTPUT:

list of polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: H = Polyomino([(-1, 1), (-1, 4), (-1, 7), (0, 0), (0, 1), (0, 2),
....: (0, 3), (0, 4), (0, 5), (0, 6), (0, 7), (0, 8), (1, 1), (1, 2),
....: (1, 3), (1, 4), (1, 5), (1, 6), (1, 7), (1, 8), (2, 0), (2, 2),
....: (2, 3), (2, 5), (2, 6), (2, 8)])
sage: solution = H.self_surrounding(8)
sage: G = sum([p.show2d() for p in solution], Graphics())                    #␣
↪needs sage.plot
```

```
sage: solution = H.self_surrounding(8, remove_incomplete_copies=False)
sage: G = sum([p.show2d() for p in solution], Graphics())                    #␣
↪needs sage.plot
```

show2d(*size=0.7*, *color='black'*, *thickness=1*)

Return a 2d Graphic object representing the polyomino.

INPUT:

- `self` – a polyomino of dimension 2
- `size` – number (default: `0.7`), the size of each square.
- `color` – color (default: `'black'`), color of the boundary line.
- `thickness` – number (default: `1`), how thick the boundary line is.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)], color='deeppink')
sage: p.show2d()                    # long time (0.5s)                    #␣
↪needs sage.plot
Graphics object consisting of 17 graphics primitives
```

show3d(*size=1*)

Return a 3d Graphic object representing the polyomino.

INPUT:

- `self` – a polyomino of dimension 3
- `size` – number (default: `1`), the size of each `1 \times 1 \times 1` cube. This does a homothety with respect to the center of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.show3d()                    # long time (2s)                      #␣
↪needs sage.plot
Graphics3d Object
```

sorted_list()

Return the color of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.sorted_list()
[(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)]
```

translated_copies(*box*)

Return an iterator over the translated images of `self` inside a polyomino.

INPUT:

- `box` – Polyomino or tuple of integers (size of a box)

OUTPUT:

iterator of 3d polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink
↪')
sage: for t in p.translated_copies(box=(5,8,2)): t
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color:␣
↪deeppink
Polyomino: [(0, 1, 0), (1, 1, 0), (1, 2, 0), (1, 2, 1), (1, 3, 0)], Color:␣
↪deeppink
Polyomino: [(0, 2, 0), (1, 2, 0), (1, 3, 0), (1, 3, 1), (1, 4, 0)], Color:␣
↪deeppink
Polyomino: [(0, 3, 0), (1, 3, 0), (1, 4, 0), (1, 4, 1), (1, 5, 0)], Color:␣
↪deeppink
Polyomino: [(0, 4, 0), (1, 4, 0), (1, 5, 0), (1, 5, 1), (1, 6, 0)], Color:␣
↪deeppink
Polyomino: [(0, 5, 0), (1, 5, 0), (1, 6, 0), (1, 6, 1), (1, 7, 0)], Color:␣
↪deeppink
Polyomino: [(1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 1, 1), (2, 2, 0)], Color:␣
↪deeppink
Polyomino: [(1, 1, 0), (2, 1, 0), (2, 2, 0), (2, 2, 1), (2, 3, 0)], Color:␣
↪deeppink
Polyomino: [(1, 2, 0), (2, 2, 0), (2, 3, 0), (2, 3, 1), (2, 4, 0)], Color:␣
↪deeppink
Polyomino: [(1, 3, 0), (2, 3, 0), (2, 4, 0), (2, 4, 1), (2, 5, 0)], Color:␣
↪deeppink
Polyomino: [(1, 4, 0), (2, 4, 0), (2, 5, 0), (2, 5, 1), (2, 6, 0)], Color:␣
↪deeppink
Polyomino: [(1, 5, 0), (2, 5, 0), (2, 6, 0), (2, 6, 1), (2, 7, 0)], Color:␣
↪deeppink
Polyomino: [(2, 0, 0), (3, 0, 0), (3, 1, 0), (3, 1, 1), (3, 2, 0)], Color:␣
↪deeppink
Polyomino: [(2, 1, 0), (3, 1, 0), (3, 2, 0), (3, 2, 1), (3, 3, 0)], Color:␣
↪deeppink
Polyomino: [(2, 2, 0), (3, 2, 0), (3, 3, 0), (3, 3, 1), (3, 4, 0)], Color:␣
↪deeppink
Polyomino: [(2, 3, 0), (3, 3, 0), (3, 4, 0), (3, 4, 1), (3, 5, 0)], Color:␣
↪deeppink
Polyomino: [(2, 4, 0), (3, 4, 0), (3, 5, 0), (3, 5, 1), (3, 6, 0)], Color:␣
↪deeppink
Polyomino: [(2, 5, 0), (3, 5, 0), (3, 6, 0), (3, 6, 1), (3, 7, 0)], Color:␣
↪deeppink
Polyomino: [(3, 0, 0), (4, 0, 0), (4, 1, 0), (4, 1, 1), (4, 2, 0)], Color:␣
↪deeppink
Polyomino: [(3, 1, 0), (4, 1, 0), (4, 2, 0), (4, 2, 1), (4, 3, 0)], Color:␣
↪deeppink
Polyomino: [(3, 2, 0), (4, 2, 0), (4, 3, 0), (4, 3, 1), (4, 4, 0)], Color:␣
↪deeppink
Polyomino: [(3, 3, 0), (4, 3, 0), (4, 4, 0), (4, 4, 1), (4, 5, 0)], Color:␣
↪deeppink
Polyomino: [(3, 4, 0), (4, 4, 0), (4, 5, 0), (4, 5, 1), (4, 6, 0)], Color:␣
↪deeppink
Polyomino: [(3, 5, 0), (4, 5, 0), (4, 6, 0), (4, 6, 1), (4, 7, 0)], Color:␣
↪deeppink
```

This method is independent of the translation of the polyomino:

```
sage: q = Polyomino([(0,0,0), (1,0,0)])
sage: list(q.translated_copies((2,2,1)))
```

(continues on next page)

(continued from previous page)

```
[Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray,
 Polyomino: [(0, 1, 0), (1, 1, 0)], Color: gray]
sage: q = Polyomino([(34,7,-9), (35,7,-9)])
sage: list(q.translated_copies((2,2,1)))
[Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray,
 Polyomino: [(0, 1, 0), (1, 1, 0)], Color: gray]
```

Inside smaller boxes:

```
sage: list(p.translated_copies(box=(2,2,3)))
[]
sage: list(p.translated_copies(box=(2,3,2)))
[Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color:␣
↪deeppink]
sage: list(p.translated_copies(box=(3,2,2)))
[]
sage: list(p.translated_copies(box=(1,1,1)))
[]
```

Using a Polyomino as input:

```
sage: b = Polyomino([(0,0), (0,1), (0,2), (1,0), (1,1), (1,2)])
sage: p = Polyomino([(0,0)])
sage: list(p.translated_copies(b))
[Polyomino: [(0, 0)], Color: gray,
 Polyomino: [(0, 1)], Color: gray,
 Polyomino: [(0, 2)], Color: gray,
 Polyomino: [(1, 0)], Color: gray,
 Polyomino: [(1, 1)], Color: gray,
 Polyomino: [(1, 2)], Color: gray]
```

```
sage: p = Polyomino([(0,0), (1,0), (0,1)])
sage: b = Polyomino([(0,0), (1,0), (2,0), (0,1), (1,1), (0,2)])
sage: list(p.translated_copies(b))
[Polyomino: [(0, 0), (0, 1), (1, 0)], Color: gray,
 Polyomino: [(0, 1), (0, 2), (1, 1)], Color: gray,
 Polyomino: [(1, 0), (1, 1), (2, 0)], Color: gray]
```

translated_copies_intersection(*box*)

Return the set of non empty intersections of translated images of `self` with a polyomino.

INPUT:

- `box` – Polyomino or tuple of integers (size of a box)

OUTPUT:

set of 3d polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0)], color='deeppink')
sage: sorted(sorted(a.frozenset())
....:        for a in p.translated_copies_intersection(box=(2,3)))
[[(0, 0)],
 [(0, 0), (1, 0)],
 [(0, 1)],
```

(continues on next page)

(continued from previous page)

```
 [(0, 1), (1, 1)],
 [(0, 2)],
 [(0, 2), (1, 2)],
 [(1, 0)],
 [(1, 1)],
 [(1, 2)]]
```

Using a Polyomino as input:

```
sage: b = Polyomino([(0,0), (0,1), (0,2), (1,0), (2,0)])
sage: p = Polyomino([(0,0), (1,0)])
sage: sorted(sorted(a.frozenset())
....:        for a in p.translated_copies_intersection(b))
[[(0, 0)], [(0, 0), (1, 0)], [(0, 1)], [(0, 2)], [(1, 0), (2, 0)], [(2, 0)]]
```

class sage.combinat.tiling.**TilingSolver**(*pieces*, *box*, *rotation=True*, *reflection=False*, *reusable=False*, *outside=False*)

Bases: SageObject

Tiling solver

Solve the problem of tiling a polyomino with a certain number of polyominoes.

INPUT:

- `pieces` – iterable of Polyominoes
- `box` – Polyomino or tuple of integers (size of a box)
- `rotation` – bool (default: `True`), whether to allow rotations
- `reflection` – bool (default: `False`), whether to allow reflections
- `reusable` – bool (default: `False`), whether to allow the pieces to be reused
- `outside` – bool (default: `False`), whether to allow pieces to partially go outside of the box (all non-empty intersection of the pieces with the box are considered)

EXAMPLES:

By default, rotations are allowed and reflections are not allowed:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T
Tiling solver of 3 pieces into a box of size 6
Rotation allowed: True
Reflection allowed: False
Reusing pieces allowed: False
```

Solutions are given by an iterator:

```
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
```

Another solution:

```
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
```

Tiling of a polyomino by polyominoes:

```
sage: b = Polyomino([(0,0), (1,0), (1,1), (2,1), (1,2), (2,2), (0,3), (1,3)])
sage: p = Polyomino([(0,0), (1,0)])
sage: T = TilingSolver([p], box=b, reusable=True)
sage: T.number_of_solutions()
2
```

animate(*partial=None*, *stop=None*, *size=0.75*, *axes=False*)

Return an animation of evolving solutions.

INPUT:

- `partial` – string (default: `None`), whether to include partial (incomplete) solutions. It can be one of the following:
  - `None` – include only complete solutions
  - `'common_prefix'` – common prefix between two consecutive solutions
  - `'incremental'` – one piece change at a time
- `stop` – integer (default:`None`), number of frames
- `size` – number (default: `0.75`), the size of each `1 \times 1` square. This does a homothety with respect to the center of each polyomino.
- `axes` – bool (default:`False`), whether the x and y axes are shown.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='cyan')
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: a = T.animate()                                                    #␣
↪needs sage.plot
sage: a                                 # long time, optional - imagemagick,␣
↪needs sage.plot
Animation with 10 frames
```

Include partial solutions (common prefix between two consecutive solutions):

```
sage: a = T.animate('common_prefix')                                     #␣
↪needs sage.plot
sage: a                                 # long time, optional - imagemagick,␣
↪needs sage.plot
Animation with 19 frames
```

Incremental solutions (one piece removed or added at a time):

```
sage: a = T.animate('incremental')  # long time (2s)                     #␣
↪needs sage.plot
sage: a                                 # long time (2s), optional - imagemagick,␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.plot
Animation with 123 frames
```

```
sage: a.show()                          # long time, optional - imagemagick,␣
↪needs sage.plot
```

The `show` function takes arguments to specify the delay between frames (measured in hundredths of a second, default value 20) and the number of iterations (default value 0, which means to iterate forever). To iterate 4 times with half a second between each frame:

```
sage: a.show(delay=50, iterations=4)        # long time, optional -␣
↪imagemagick, needs sage.plot
```

Limit the number of frames:

```
sage: a = T.animate('incremental', stop=13); a      # not tested              #␣
↪needs sage.plot
Animation with 13 frames
```

coord_to_int_dict()

Return a dictionary mapping coordinates to integers.

OUTPUT:

dict

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: A = T.coord_to_int_dict()
sage: sorted(A.items())
[((0, 0, 0), 3), ((0, 0, 1), 4), ((0, 0, 2), 5),
 ((0, 0, 3), 6), ((0, 0, 4), 7), ((0, 0, 5), 8)]
```

Reusable pieces:

```
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)
sage: B = T.coord_to_int_dict()
sage: sorted(B.items())
[((0, 0), 0), ((0, 1), 1), ((1, 0), 2), ((1, 1), 3),
 ((2, 0), 4), ((2, 1), 5)]
```

dlx_solver()

Return the sage DLX solver of that tiling problem.

OUTPUT:

DLX Solver

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.dlx_solver()
Dancing links solver for 9 columns and 15 rows
```

int_to_coord_dict()

Return a dictionary mapping integers to coordinates.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: B = T.int_to_coord_dict()
sage: sorted(B.items())
[(3, (0, 0, 0)), (4, (0, 0, 1)), (5, (0, 0, 2)),
 (6, (0, 0, 3)), (7, (0, 0, 4)), (8, (0, 0, 5))]
```

Reusable pieces:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)
sage: B = T.int_to_coord_dict()
sage: sorted(B.items())
[(0, (0, 0)), (1, (0, 1)), (2, (1, 0)),
 (3, (1, 1)), (4, (2, 0)), (5, (2, 1))]
```

is_suitable()

Return whether the volume of the box is equal to sum of the volume of the polyominoes and the number of rows sent to the DLX solver is larger than zero.

If these conditions are not verified, then the problem is not suitable in the sense that there are no solution.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.is_suitable()
True
sage: T = TilingSolver([p,q,r], box=(1,1,7))
sage: T.is_suitable()
False
```

nrows_per_piece()

Return the number of rows necessary by each piece.

OUTPUT:

list

EXAMPLES:

```
sage: from sage.games.quantumino import QuantuminoSolver
sage: q = QuantuminoSolver(0)
sage: T = q.tiling_solver()
sage: T.nrows_per_piece()              # long time (10s)
[360, 360, 360, 360, 360, 180, 180, 672, 672, 360, 360, 180, 180, 360, 360,␣
↪180]
```

number_of_solutions()

Return the number of distinct solutions.

OUTPUT:

integer

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0)])
sage: q = Polyomino([(0,0), (0,1)])
sage: r = Polyomino([(0,0), (0,1), (0,2)])
sage: T = TilingSolver([p,q,r], box=(1,6))
sage: T.number_of_solutions()
6
```

```
sage: T = TilingSolver([p,q,r], box=(1,7))
sage: T.number_of_solutions()
0
```

pieces()

Return the list of pieces.

OUTPUT:

list of 3d polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: for p in T._pieces: p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1), (0, 0, 2)], Color: gray
```

row_to_polyomino(*row_number*)

Return a polyomino associated to a row.

INPUT:

- `row_number` – integer, the i-th row

OUTPUT:

polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)], color='blue')
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)], color='red')
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: len(T.rows())
16
```

```
sage: T.row_to_polyomino(7)
Polyomino: [(0, 0, 2), (1, 0, 1), (1, 0, 2)], Color: blue
```

```
sage: T.row_to_polyomino(13)
Polyomino: [(0, 0, 1), (1, 0, 1), (1, 0, 2)], Color: red
```

rows()

Creation of the rows

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: rows = T.rows()
sage: for row in rows: row
[0, 3]
[0, 4]
[0, 5]
[0, 6]
[0, 7]
[0, 8]
[1, 3, 4]
[1, 4, 5]
[1, 5, 6]
[1, 6, 7]
[1, 7, 8]
[2, 3, 4, 5]
[2, 4, 5, 6]
[2, 5, 6, 7]
[2, 6, 7, 8]
```

rows_for_piece(*i*, *mod_box_isometries=False*)

Return the rows for the i-th piece.

INPUT:

- `i` – integer, the i-th piece
- `mod_box_isometries` – bool (default: `False`), whether to consider only rows for positions up to the action of the quotient the group of isometries of the n-cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where are the a_i are assumed to be distinct.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
```

(continues on next page)

(continued from previous page)

```
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.rows_for_piece(0)
[[0, 3], [0, 4], [0, 5], [0, 6], [0, 7], [0, 8]]
sage: T.rows_for_piece(1)
[[1, 3, 4], [1, 4, 5], [1, 5, 6], [1, 6, 7], [1, 7, 8]]
sage: T.rows_for_piece(2)
[[2, 3, 4, 5], [2, 4, 5, 6], [2, 5, 6, 7], [2, 6, 7, 8]]
```

Less rows when using `mod_box_isometries=True`:

```
sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)])
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)])
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: T.rows_for_piece(0)
[[0, 2, 3, 5],
 [0, 3, 4, 6],
 [0, 2, 3, 6],
 [0, 3, 4, 7],
 [0, 2, 5, 6],
 [0, 3, 6, 7],
 [0, 3, 5, 6],
 [0, 4, 6, 7]]
sage: T.rows_for_piece(0, mod_box_isometries=True)
[[0, 2, 3, 5], [0, 3, 4, 6]]
sage: T.rows_for_piece(1, mod_box_isometries=True)
[[1, 2, 3, 5], [1, 3, 4, 6]]
```

solve (*partial=None*)

Return an iterator of list of polyominoes that are an exact cover of the box.

INPUT:

- `partial` – string (default: `None`), whether to include partial (incomplete) solutions. It can be one of the following:
  - `None` – include only complete solution
  - `'common_prefix'` – common prefix between two consecutive solutions
  - `'incremental'` – one piece change at a time

OUTPUT:

iterator of list of polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
```

(continues on next page)

(continued from previous page)

```
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 2), (0, 0, 3), (0, 0, 4)], Color: gray
Polyomino: [(0, 0, 5)], Color: gray
```

Including the partial solutions:

```
sage: it = T.solve(partial='common_prefix')
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
sage: for p in next(it): p
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 2), (0, 0, 3), (0, 0, 4)], Color: gray
Polyomino: [(0, 0, 5)], Color: gray
```

Colors are preserved when the polyomino can be reused:

```
sage: p = Polyomino([(0,0,0)], color='yellow')
sage: q = Polyomino([(0,0,0), (0,0,1)], color='yellow')
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)], color='yellow')
sage: T = TilingSolver([p,q,r], box=(1,1,6), reusable=True)
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: yellow
Polyomino: [(0, 0, 1)], Color: yellow
Polyomino: [(0, 0, 2)], Color: yellow
Polyomino: [(0, 0, 3)], Color: yellow
Polyomino: [(0, 0, 4)], Color: yellow
Polyomino: [(0, 0, 5)], Color: yellow
```

space()

Return an iterator over all the non negative integer coordinates contained in the space to tile.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: list(T.space())
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 0, 4), (0, 0, 5)]
```

starting_rows()

Return the starting rows for each piece.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.starting_rows()
[0, 6, 11, 15]
```

sage.combinat.tiling.**ncube_isometry_group**(*n*, *orientation_preserving=True*)

Return the isometry group of the n-cube as a list of matrices.

INPUT:

- `n` – positive integer, dimension of the space
- `orientation_preserving` – bool (default: `True`), whether the orientation is preserved

OUTPUT:

list of matrices

EXAMPLES:

```
sage: from sage.combinat.tiling import ncube_isometry_group
sage: ncube_isometry_group(2)
[
[1 0]  [ 0  1]  [-1  0]  [ 0 -1]
[0 1], [-1  0], [ 0 -1], [ 1  0]
]
sage: ncube_isometry_group(2, orientation_preserving=False)
[
[1 0]  [ 0 -1]  [ 1  0]  [ 0  1]  [0 1]  [-1  0]  [ 0 -1]  [-1  0]
[0 1], [-1  0], [ 0 -1], [-1  0], [1 0], [ 0 -1], [ 1  0], [ 0  1]
]
```

There are 24 orientation preserving isometries of the 3-cube:

```
sage: ncube_isometry_group(3)
[
[1 0 0]  [ 1  0  0]  [ 1  0  0]  [ 0  1  0]  [0 1 0]  [ 0  0  1]
[0 1 0]  [ 0  0  1]  [ 0  0 -1]  [-1  0  0]  [0 0 1]  [ 0 -1  0]
[0 0 1], [ 0 -1  0], [ 0  1  0], [ 0  0  1], [1 0 0], [ 1  0  0],

[-1  0  0]  [ 0 -1  0]  [-1  0  0]  [-1  0  0]  [ 0 -1  0]  [ 0  0 -1]
[ 0 -1  0]  [ 0  0 -1]  [ 0  0 -1]  [ 0  1  0]  [ 0  0  1]  [ 1  0  0]
[ 0  0  1], [ 1  0  0], [ 0 -1  0], [ 0  0 -1], [-1  0  0], [ 0 -1  0],

[ 0  1  0]  [ 0  0  1]  [0 0 1]  [ 0 -1  0]  [ 0  0 -1]  [-1  0  0]
[ 1  0  0]  [ 0  1  0]  [1 0 0]  [ 1  0  0]  [ 0  1  0]  [ 0  0  1]
[ 0  0 -1], [-1  0  0], [0 1 0], [ 0  0  1], [ 1  0  0], [ 0  1  0],

[ 0 -1  0]  [ 0  0 -1]  [ 0  0  1]  [ 1  0  0]  [ 0  0 -1]  [ 0  1  0]
[-1  0  0]  [-1  0  0]  [-1  0  0]  [ 0 -1  0]  [ 0 -1  0]  [ 0  0 -1]
[ 0  0 -1], [ 0  1  0], [ 0 -1  0], [ 0  0 -1], [-1  0  0], [-1  0  0]
]
```

sage.combinat.tiling.**ncube_isometry_group_cosets**(*orientation_preserving=True*)

Return the quotient of the isometry group of the n-cube by the the isometry group of the rectangular parallelepiped.

INPUT:

- `n` – positive integer, dimension of the space
- `orientation_preserving` – bool (default: `True`), whether the orientation is preserved

OUTPUT:

list of cosets, each coset being a sorted list of matrices

EXAMPLES:

```
sage: from sage.combinat.tiling import ncube_isometry_group_cosets
sage: sorted(ncube_isometry_group_cosets(2))
[[
[-1  0]  [1 0]
[ 0 -1], [0 1]
], [
[ 0 -1]  [ 0  1]
[ 1  0], [-1  0]
]]
sage: sorted(ncube_isometry_group_cosets(2, False))
[[
[-1  0]  [-1  0]  [ 1  0]  [1 0]
[ 0 -1], [ 0  1], [ 0 -1], [0 1]
], [
[ 0 -1]  [ 0 -1]  [ 0  1]  [0 1]
[-1  0], [ 1  0], [-1  0], [1 0]
]]
```

```
sage: sorted(ncube_isometry_group_cosets(3))
[[
[-1  0  0]  [-1  0  0]  [ 1  0  0]  [1 0 0]
[ 0 -1  0]  [ 0  1  0]  [ 0 -1  0]  [0 1 0]
[ 0  0  1], [ 0  0 -1], [ 0  0 -1], [0 0 1]
], [
[-1  0  0]  [-1  0  0]  [ 1  0  0]  [ 1  0  0]
[ 0  0 -1]  [ 0  0  1]  [ 0  0 -1]  [ 0  0  1]
[ 0 -1  0], [ 0  1  0], [ 0  1  0], [ 0 -1  0]
], [
[ 0 -1  0]  [ 0 -1  0]  [ 0  1  0]  [ 0  1  0]
[-1  0  0]  [ 1  0  0]  [-1  0  0]  [ 1  0  0]
[ 0  0 -1], [ 0  0  1], [ 0  0  1], [ 0  0 -1]
], [
[ 0 -1  0]  [ 0 -1  0]  [ 0  1  0]  [0 1 0]
[ 0  0 -1]  [ 0  0  1]  [ 0  0 -1]  [0 0 1]
[ 1  0  0], [-1  0  0], [-1  0  0], [1 0 0]
], [
[ 0  0 -1]  [ 0  0 -1]  [ 0  0  1]  [0 0 1]
[-1  0  0]  [ 1  0  0]  [-1  0  0]  [1 0 0]
[ 0  1  0], [ 0 -1  0], [ 0 -1  0], [0 1 0]
], [
[ 0  0 -1]  [ 0  0 -1]  [ 0  0  1]  [ 0  0  1]
[ 0 -1  0]  [ 0  1  0]  [ 0 -1  0]  [ 0  1  0]
[-1  0  0], [ 1  0  0], [ 1  0  0], [-1  0  0]
]]
```

5.1.350 Transitive ideal closure tool

sage.combinat.tools.**transitive_ideal**(f, x)

Return a list of all elements reachable from x in the abstract reduction system whose reduction relation is given by the function f.

In more elementary terms:

If S is a set, and f is a function sending every element of S to a list of elements of S, then we can define a digraph on the vertex set S by drawing an edge from s to t for every $s \in S$ and every $t \in f(s)$.

If $x \in S$, then an element $y \in S$ is said to be reachable from x if there is a path $x \to y$ in this graph.

Given f and x, this method computes the list of all elements of S reachable from x.

Note that if there are infinitely many such elements, then this method will never halt.

For more powerful versions, see *sage.combinat.backtrack*

EXAMPLES:

```
sage: f = lambda x: [x-1] if x > 0 else []
sage: sage.combinat.tools.transitive_ideal(f, 10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

5.1.351 Combinatorial triangles for posets and fans

This provides several classes and methods to convert between them. Elements of the classes are polynomials in two variables x and y, possibly with other parameters. The conversion methods amount to specific invertible rational change-of-variables involving x and y.

These polynomial are called triangles because their supports, the sets of exponents where their coefficients can be non-zero, have a triangular shape.

The M-triangle class is motivated by the generating series of Möbius numbers for graded posets. A typical example is:

```
sage: W = SymmetricGroup(4)                                                 #␣
↪needs sage.groups
sage: posets.NoncrossingPartitions(W).M_triangle()                          #␣
↪needs sage.graphs sage.groups
M: x^3*y^3 - 6*x^2*y^3 + 6*x^2*y^2 + 10*x*y^3 - 16*x*y^2
- 5*y^3 + 6*x*y + 10*y^2 - 6*y + 1
sage: unicode_art(_)                                                        #␣
↪needs sage.graphs sage.groups sage.modules
⎛ -5  10  -6   1⎞
⎜ 10 -16   6   0⎟
⎜ -6   6   0   0⎟
⎝  1   0   0   0⎠
```

The F-triangle class is motivated by the generating series of pure simplicial complexes endowed with a distinguished facet. One can also think about complete fans endowed with a distinguished maximal cone. A typical example is:

```
sage: # needs sage.graphs sage.modules
sage: C = ClusterComplex(['A',3])
sage: f = C.greedy_facet()
sage: C.F_triangle(f)
F: 5*x^3 + 5*x^2*y + 3*x*y^2 + y^3 + 10*x^2 + 8*x*y + 3*y^2 + 6*x + 3*y + 1
sage: unicode_art(_)
```

(continues on next page)

(continued from previous page)

```
[ 1  0  0  0]
[ 3  3  0  0]
[ 3  8  5  0]
[ 1  6 10  5]
```

The H-triangles are related to the F-triangles by a relationship similar to the classical link between the f-vector and the h-vector of a simplicial complex.

The Gamma-triangles are related to the H-triangles by an analog of the relationship between gamma-vectors and h-vectors of flag simplicial complexes.

class sage.combinat.triangles_FHM.**F_triangle**(*poly*, *variables=None*)

Bases: *Triangle*

Class for the F-triangles.

h()

Return the associated H-triangle.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import F_triangle
sage: x,y = polygens(ZZ,'x,y')
sage: ft = F_triangle(1+x+y)
sage: ft.h()
H: x*y + 1
```

m()

Return the associated M-triangle.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygens(ZZ,'x,y')
sage: H_triangle(1+x*y).f()
F: x + y + 1
sage: _.m()
M: x*y - y + 1

sage: H_triangle(x^2*y^2 + 2*x*y + x + 1).f()
F: 2*x^2 + 2*x*y + y^2 + 3*x + 2*y + 1
sage: _.m()
M: x^2*y^2 - 3*x*y^2 + 3*x*y + 2*y^2 - 3*y + 1
```

vector()

Return the f-vector as a polynomial in one variable.

This is obtained by letting $y = x$.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import F_triangle
sage: x, y = polygen(ZZ,'x,y')
sage: ft = 2*x^2 + 2*x*y + y^2 + 3*x + 2*y + 1
sage: F_triangle(ft).vector()
5*x^2 + 5*x + 1
```

class sage.combinat.triangles_FHM.**Gamma_triangle**(*poly*, *variables=None*)

Bases: *Triangle*

Class for the Gamma-triangles.

h()

Return the associated H-triangle.

The transition between Gamma-triangles and H-triangles is defined by

$$H(x,y) = (1+x)^d \sum_{0\le i;0\le j\le d-2i} \gamma_{i,j} \left(\frac{x}{(1+x)^2}\right)^i \left(\frac{1+xy}{1+x}\right)^j$$

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import Gamma_triangle
sage: x, y = polygen(ZZ,'x,y')
sage: g = y**2 + x
sage: Gamma_triangle(g).h()
H: x^2*y^2 + 2*x*y + x + 1

sage: a, b = polygen(ZZ, 'a, b')
sage: x, y = polygens(a.parent(),'x,y')
sage: g = Gamma_triangle(y**3+a*x*y+b*x,(x,y))
sage: hh = g.h()
sage: hh.gamma() == g
True
```

vector()

Return the gamma-vector as a polynomial in one variable.

This is obtained by letting $y = 1$.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import Gamma_triangle
sage: x, y = polygen(ZZ,'x,y')
sage: gt = y**2 + x
sage: Gamma_triangle(gt).vector()
x + 1
```

class sage.combinat.triangles_FHM.**H_triangle**(*poly*, *variables=None*)

Bases: *Triangle*

Class for the H-triangles.

f()

Return the associated F-triangle.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygens(ZZ,'x,y')
sage: H_triangle(1+x*y).f()
F: x + y + 1
sage: H_triangle(x^2*y^2 + 2*x*y + x + 1).f()
F: 2*x^2 + 2*x*y + y^2 + 3*x + 2*y + 1
sage: flo = H_triangle(1+4*x+2*x**2+x*y*(4+8*x)+
....:   x**2*y**2*(6+4*x)+4*(x*y)**3+(x*y)**4).f(); flo
```

(continues on next page)

(continued from previous page)

```
F: 7*x^4 + 12*x^3*y + 10*x^2*y^2 + 4*x*y^3 + y^4 + 20*x^3
+ 28*x^2*y + 16*x*y^2 + 4*y^3 + 20*x^2 + 20*x*y
+ 6*y^2 + 8*x + 4*y + 1
sage: flo(-1-x,-1-y) == flo
True
```

gamma()

Return the associated Gamma-triangle.

In some cases, this is a more condensed way to encode the same amount of information.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygen(ZZ,'x,y')
sage: ht = x**2*y**2 + 2*x*y + x + 1
sage: H_triangle(ht).gamma()
Γ: y^2 + x

sage: W = SymmetricGroup(5)                                                    #␣
↪needs sage.groups
sage: P = posets.NoncrossingPartitions(W)                                      #␣
↪needs sage.graphs sage.groups
sage: P.M_triangle().h().gamma()                                               #␣
↪needs sage.graphs sage.groups
Γ: y^4 + 3*x*y^2 + 2*x^2 + 2*x*y + x
```

m()

Return the associated M-triangle.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: h = polygen(ZZ, 'h')
sage: x, y = polygens(h.parent(),'x,y')
sage: ht = H_triangle(x^2*y^2 + 2*x*y + 2*x*h - 4*x + 1, variables=[x,y])
sage: ht.m()
M: x^2*y^2 + (-2*h + 2)*x*y^2 + (2*h - 2)*x*y
+ (2*h - 3)*y^2 + (-2*h + 2)*y + 1
```

transpose()

Return the transposed H-triangle.

OUTPUT:

another H-triangle

This operation is an involution. When seen as a matrix, it performs a symmetry with respect to the northwest-southeast diagonal.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygens(ZZ,'x,y')
sage: H_triangle(1+x*y).transpose()
H: x*y + 1
sage: H_triangle(x^2*y^2 + 2*x*y + x + 1).transpose()
H: x^2*y^2 + x^2*y + 2*x*y + 1
```

vector()

Return the h-vector as a polynomial in one variable.

This is obtained by letting $y = 1$.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygen(ZZ,'x,y')
sage: ht = x**2*y**2 + 2*x*y + x + 1
sage: H_triangle(ht).vector()
x^2 + 3*x + 1
```

class sage.combinat.triangles_FHM.**M_triangle**(*poly*, *variables=None*)

Bases: *Triangle*

Class for the M-triangles.

This is motivated by generating series of Möbius numbers of graded posets.

EXAMPLES:

```
sage: x, y = polygens(ZZ, 'x,y')
sage: P = Poset({2: [1]})                                                    #␣
↪needs sage.graphs
sage: P.M_triangle()                                                         #␣
↪needs sage.graphs
M: x*y - y + 1
```

dual()

Return the dual M-triangle.

This is the M-triangle of the dual poset, hence an involution.

When seen as a matrix, this performs a symmetry with respect to the northwest-southeast diagonal.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import  M_triangle
sage: x, y = polygens(ZZ, 'x,y')
sage: mt = M_triangle(x*y - y + 1)
sage: mt.dual() == mt
True
```

f()

Return the associated F-triangle.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import M_triangle
sage: x, y = polygens(ZZ,'x,y')
sage: M_triangle(1-y+x*y).f()
F: x + y + 1
```

h()

Return the associated H-triangle.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import M_triangle
sage: x, y = polygens(ZZ,'x,y')
sage: M_triangle(1-y+x*y).h()
H: x*y + 1
```

transmute()

Return the image of `self` by an involution.

OUTPUT:

another M-triangle

The involution is defined by converting to an H-triangle, transposing the matrix, and then converting back to an M-triangle.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import  M_triangle
sage: x, y = polygens(ZZ, 'x,y')
sage: nc3 = x^2*y^2 - 3*x*y^2 + 3*x*y + 2*y^2 - 3*y + 1
sage: m = M_triangle(nc3)
sage: m2 = m.transmute(); m2                                                #␣
↪needs sage.libs.flint
M: 2*x^2*y^2 - 3*x*y^2 + 2*x*y + y^2 - 2*y + 1
sage: m2.transmute() == m                                                   #␣
↪needs sage.libs.flint
True
```

class sage.combinat.triangles_FHM.**Triangle**(*poly*, *variables=None*)

Bases: SageObject

Common class for different kinds of triangles.

This serves as a base class for F-triangles, H-triangles, M-triangles and Gamma-triangles.

The user should use these subclasses directly.

The input is a polynomial in two variables. One can also give a polynomial with more variables and specify two chosen variables.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import Triangle
sage: x, y = polygens(ZZ, 'x,y')
sage: ht = Triangle(1+4*x+2*x*y)
sage: unicode_art(ht)                                                       #␣
↪needs sage.modules
⎛0 2⎞
⎝1 4⎠
```

matrix()

Return the associated matrix for display.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygens(ZZ, 'x,y')
sage: h = H_triangle(1+2*x*y)
sage: h.matrix()                                                            #␣
↪needs sage.modules
```

(continues on next page)

(continued from previous page)

```
[0 2]
[1 0]
```

polynomial()

Return the triangle as a bare polynomial.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygens(ZZ, 'x,y')
sage: h = H_triangle(1+2*x*y)
sage: h.polynomial()
2*x*y + 1
```

truncate(d)

Return the truncated triangle.

INPUT:

- d – integer

As a polynomial, this means that all monomials with a power of either x or y greater than or equal to d are dismissed.

EXAMPLES:

```
sage: from sage.combinat.triangles_FHM import H_triangle
sage: x, y = polygens(ZZ, 'x,y')
sage: h = H_triangle(1+2*x*y)
sage: h.truncate(2)
H: 2*x*y + 1
```

5.1.352 Tuples

class sage.combinat.tuple.**Tuples**(S, k)

Bases: Parent, UniqueRepresentation

Return the enumerated set of ordered tuples of S of length k.

An ordered tuple of length k of set is an ordered selection with repetition and is represented by a list of length k containing elements of set.

EXAMPLES:

```
sage: S = [1,2]
sage: Tuples(S,3).list()
[(1, 1, 1), (2, 1, 1), (1, 2, 1), (2, 2, 1), (1, 1, 2),
 (2, 1, 2), (1, 2, 2), (2, 2, 2)]
sage: mset = ["s","t","e","i","n"]
sage: Tuples(mset,2).list()
[('s', 's'), ('t', 's'), ('e', 's'), ('i', 's'), ('n', 's'),
 ('s', 't'), ('t', 't'), ('e', 't'), ('i', 't'), ('n', 't'),
 ('s', 'e'), ('t', 'e'), ('e', 'e'), ('i', 'e'), ('n', 'e'),
 ('s', 'i'), ('t', 'i'), ('e', 'i'), ('i', 'i'), ('n', 'i'),
 ('s', 'n'), ('t', 'n'), ('e', 'n'), ('i', 'n'), ('n', 'n')]
```

```
sage: K.<a> = GF(4, 'a')                                                    #␣
↪needs sage.rings.finite_rings
sage: mset = sorted((x for x in K if x != 0), key=str)                      #␣
↪needs sage.rings.finite_rings
sage: Tuples(mset, 2).list()                                                #␣
↪needs sage.rings.finite_rings
[(1, 1),     (a, 1),     (a + 1, 1),
 (1, a),     (a, a),     (a + 1, a),
 (1, a + 1), (a, a + 1), (a + 1, a + 1)]
```

cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
sage: S = [1,1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
```

sage.combinat.tuple.**Tuples_sk**

alias of *Tuples*

class sage.combinat.tuple.**UnorderedTuples**(S, k)

Bases: Parent, UniqueRepresentation

Return the enumerated set of unordered tuples of S of length k.

An unordered tuple of length k of set is a unordered selection with repetitions of set and is represented by a sorted list of length k containing elements from set.

EXAMPLES:

```
sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)]
sage: UnorderedTuples(["a","b","c"],2).list()
[('a', 'a'), ('a', 'b'), ('a', 'c'), ('b', 'b'), ('b', 'c'),
 ('c', 'c')]
```

cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: UnorderedTuples(S,2).cardinality()
15
```

sage.combinat.tuple.**UnorderedTuples_sk**

alias of *UnorderedTuples*

5.1.353 Introduction to combinatorics in Sage

This thematic tutorial is a translation by Hugh Thomas of the combinatorics chapter written by Nicolas M. Thiéry in the book "Calcul Mathématique avec Sage" [CMS2012]. It covers mainly the treatment in Sage of the following combinatorial problems: enumeration (how many elements are there in a set S?), listing (generate all the elements of S, or iterate through them), and random selection (choosing an element at random from a set S according to a given distribution, for example the uniform distribution). These questions arise naturally in the calculation of probabilities (what is the probability in poker of obtaining a straight or a four-of-a-kind of aces?), in statistical physics, and also in computer algebra (the number of elements in a finite field), or in the analysis of algorithms. Combinatorics covers a much wider domain (partial orders, representation theory, ...) for which we only give a few pointers towards the possibilities offered by Sage.

Todo: Add link to some thematic tutorial on graphs

A characteristic of computational combinatorics is the profusion of types of objects and sets that one wants to manipulate. It would be impossible to describe them all or, a fortiori, to implement them all. After some *Initial examples*, this chapter illustrates the underlying method: supplying the basic building blocks to describe common combinatorial sets *Common enumerated sets*, tools for combining them to construct new examples *Constructions*, and generic algorithms for solving uniformly a large class of problems *Generic algorithms*.

This is a domain in which Sage has much more extensive capabilities than most computer algebra systems, and it is rapidly expanding; at the same time, it is still quite new, and has many unnecessary limitations and incoherences.

Initial examples

Poker and probability

We begin by solving a classic problem: enumerating certain combinations of cards in the game of poker, in order to deduce their probability.

A card in a poker deck is characterized by a suit (hearts, diamonds, spades, or clubs) and a value (2, 3, ..., 10, jack, queen, king, ace). The game is played with a full deck, which consists of the Cartesian product of the set of suits and the set of values:

$$\text{Cards} = \text{Suits} \times \text{Values} = \{(s, v) \mid s \in \text{Suits} \text{ et } v \in \text{Values}\}.$$

We construct these examples in Sage:

```
sage: Suits = Set(["Hearts", "Diamonds", "Spades", "Clubs"])
sage: Values = Set([2, 3, 4, 5, 6, 7, 8, 9, 10,
....:               "Jack", "Queen", "King", "Ace"])
sage: Cards = cartesian_product([Values, Suits])
```

There are 4 suits and 13 possible values, and therefore $4 \times 13 = 52$ cards in the poker deck:

```
sage: Suits.cardinality()
4
sage: Values.cardinality()
13
sage: Cards.cardinality()
52
```

Draw a card at random:

```
sage: Cards.random_element()                          # random
(6, 'Clubs')
```

Now we can define a set of cards:

```
sage: Set([Cards.random_element(), Cards.random_element()])  # random
{(2, 'Hearts'), (4, 'Spades')}
```

This problem should eventually disappear: it is planned to change the implementation of Cartesian products so that their elements are immutable by default.

Returning to our main topic, we will be considering a simplified version of poker, in which each player directly draws five cards, which form his *hand*. The cards are all distinct and the order in which they are drawn is irrelevant; a hand is therefore a subset of size 5 of the set of cards. To draw a hand at random, we first construct the set of all possible hands, and then we ask for a randomly chosen element:

```
sage: Hands = Subsets(Cards, 5)
sage: Hands.random_element()                          # random
{(4, 'Hearts', 4), (9, 'Diamonds'), (8, 'Spades'),
 (9, 'Clubs'), (7, 'Hearts')}
```

The total number of hands is given by the number of subsets of size 5 of a set of size 52, which is given by the binomial coefficient $\binom{52}{5}$:

```
sage: binomial(52,5)
2598960
```

One can also ignore the method of calculation, and simply ask for the size of the set of hands:

```
sage: Hands.cardinality()
2598960
```

The strength of a poker hand depends on the particular combination of cards present. One such combination is the *flush*; this is a hand all of whose cards have the same suit. (In principle, straight flushes should be excluded; this will be the goal of an exercise given below.) Such a hand is therefore characterized by the choice of five values from among the thirteen possibilities, and the choice of one of four suits. We will construct the set of all flushes, so as to determine how many there are:

```
sage: Flushes = cartesian_product([Subsets(Values, 5), Suits])
sage: Flushes.cardinality()
5148
```

The probability of obtaining a flush when drawing a hand at random is therefore:

```
sage: Flushes.cardinality()  / Hands.cardinality()
33/16660
```

or about two in a thousand:

```
sage: 1000.0 * Flushes.cardinality()  / Hands.cardinality()
1.98079231692677
```

We will now attempt a little numerical simulation. The following function tests whether a given hand is a flush or not:

```
sage: def is_flush(hand):
....:     return len(set(suit for (val, suit) in hand)) == 1
```

We now draw 10000 hands at random, and count the number of flushes obtained (this takes about 10 seconds):

```
sage: n = 10000
sage: nflush = 0
sage: for i in range(n):                                # long time
....:     hand = Hands.random_element()
....:     if is_flush(hand):
....:         nflush += 1
sage: n, nflush                                      # random
(10000, 18)
```

Exercises

A hand containing four cards of the same value is called a *four of a kind*. Construct the set of four of a kind hands (Hint: use `Arrangements` to choose a pair of distinct values at random, then choose a suit for the first value). Calculate the number of four of a kind hand, list them, and then determine the probability of obtaining a four of a kind when drawing a hand at random.

A hand all of whose cards have the same suit, and whose values are consecutive, is called a *straight flush* rather than a *flush*. Count the number of straight flushes, and then deduce the correct probability of obtaining a flush when drawing a hand at random.

Calculate the probability of each of the poker hands (see Wikipedia article Poker_hands), and compare them with the results of simulations.

Enumeration of trees using generating functions

In this section, we discuss the example of complete binary trees, and illustrate in this context many techniques of enumeration in which formal power series play a natural role. These techniques are quite general, and can be applied whenever the combinatorial objects in question admit a recursive definition (grammar) (see *Species, decomposable combinatorial classes* for an automated treatment). The goal is not a formal presentation of these methods; the calculations are rigorous, but most of the justifications will be skipped.

A *complete binary tree* is either a leaf L, or a node to which two complete binary trees are attached (see *Figure: The five complete binary trees with four leaves*).

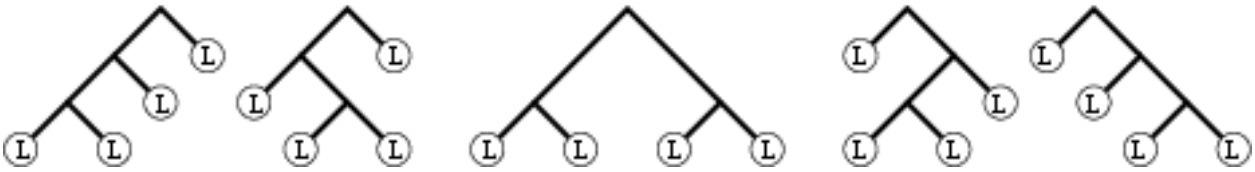

Fig. 1: Figure: The five complete binary trees with four leaves

Exercise: enumeration of binary trees

Find by hand all the complete binary trees with $n = 1, 2, 3, 4, 5$ leaves (see *Exercise: complete binary tree iterator* to find them using `Sage`).

Our goal is to determine the number c_n of complete binary trees with n leaves (in this section, except when explicitly stated otherwise, "trees" always means complete binary trees). This is a typical situation in which one is not only interested in a single set, but in a family of sets, typically parameterized by $n \in \mathbf{N}$.

According to the solution of *Exercise: enumeration of binary trees*, the first terms are given by $c_1, \ldots, c_5 = 1, 1, 2, 5, 14$. The simple fact of knowing these few numbers is already very valuable. In fact, this permits research in a gold mine of information: the Online Encyclopedia of Integer Sequences, commonly called "Sloane", the name of its principal author, which contains more than 190000 sequences of integers:

```
sage: oeis([1,1,2,5,14])                                  # optional -- internet
0: A000108: Catalan numbers: ...
1: ...
2: ...
```

The result suggests that the trees are counted by one of the most famous sequences, the Catalan numbers. Looking through the references supplied by the Encyclopedia, we see that this is really the case: the few numbers above form a digital fingerprint of our objects, which enable us to find, in a few seconds, a precise result from within an abundant literature.

Our next goal is to recover this result using Sage. Let C_n be the set of trees with n leaves, so that $c_n = |C_n|$; by convention, we will define $C_0 = \emptyset$ and $c_0 = 0$. The set of all trees is then the disjoint union of the sets C_n:

$$C = \biguplus_{n \in \mathbb{N}} C_n \,.$$

Having named the set C of all trees, we can translate the recursive definition of trees into a set-theoretic equation:

$$C \quad \approx \quad \{\mathrm{L}\} \quad \uplus \quad C \times C \,.$$

In words: a tree t (which is by definition in C) is either a leaf (so in $\{\mathrm{L}\}$) or a node to which two trees t_1 and t_2 have been attached, and which we can therefore identify with the pair (t_1, t_2) (in the Cartesian product $C \times C$).

The founding idea of algebraic combinatorics, introduced by Euler in a letter to Goldbach of 1751 to treat a similar problem , is to manipulate all the numbers c_n simultaneously, by encoding them as coefficients in a formal power series, called the *generating function* of the c_n's:

$$C(z) = \sum_{n \in \mathbb{N}} c_n z^n \,,$$

where z is a formal variable (which means that we do not have to worry about questions of convergence). The beauty of this idea is that set-theoretic operations $(A \uplus B, A \times B)$ translate naturally into algebraic operations on the corresponding series $(A(z) + B(z), A(z) \cdot B(z))$, in such a way that the set-theoretic equation satisfied by C can be translated directly into an algebraic equation satisfied by $C(z)$:

$$C(z) = z + C(z) \cdot C(z) \,.$$

Now we can solve this equation with Sage. In order to do so, we introduce two variables, C and z, and we define the equation:

```
sage: C, z = var('C,z')                                                    #␣
↪needs sage.symbolic
sage: sys = [ C == z + C*C ]                                               #␣
↪needs sage.symbolic
```

There are two solutions, which happen to have closed forms:

```
sage: sol = solve(sys, C, solution_dict=True); sol                         #␣
↪needs sage.symbolic
[{C: -1/2*sqrt(-4*z + 1) + 1/2}, {C: 1/2*sqrt(-4*z + 1) + 1/2}]
sage: s0 = sol[0][C]; s1 = sol[1][C]                                       #␣
↪needs sage.symbolic
```

and whose Taylor series begin as follows:

```
sage: s0.series(z, 6)                                                          #␣
↪needs sage.symbolic
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + Order(z^6)
sage: s1.series(z, 6)                                                          #␣
↪needs sage.symbolic
1 + (-1)*z + (-1)*z^2 + (-2)*z^3 + (-5)*z^4 + (-14)*z^5
+ Order(z^6)
```

The second solution is clearly aberrant, while the first one gives the expected coefficients. Therefore, we set:

```
sage: C = s0                                                                   #␣
↪needs sage.symbolic
```

We can now calculate the next terms:

```
sage: C.series(z, 11)                                                          #␣
↪needs sage.symbolic
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + 42*z^6 +
132*z^7 + 429*z^8 + 1430*z^9 + 4862*z^10 + Order(z^11)
```

or calculate, more or less instantaneously, the 100-th coefficient:

```
sage: C.series(z, 101).coefficient(z,100)                                      #␣
↪needs sage.symbolic
227508830794229349661819540395688853956041682601541047340
```

It is unfortunate to have to recalculate everything if at some point we wanted the 101-st coefficient. Lazy power series (see `sage.rings.lazy_series_ring`) come into their own here, in that one can define them from a system of equations without solving it, and, in particular, without needing a closed form for the answer. We begin by defining the ring of lazy power series:

```
sage: L.<z> = LazyPowerSeriesRing(QQ)
```

Then we create a "free" power series, which we name, and which we then define by a recursive equation:

```
sage: C = L.undefined(valuation=1)
sage: C.define(z + C * C)
```

```
sage: [C.coefficient(i) for i in range(11)]
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

At any point, one can ask for any coefficient without having to redefine C:

```
sage: C.coefficient(100)
227508830794229349661819540395688853956041682601541047340
sage: C.coefficient(200)
1290131580644291140012229076696766751343495305527288824998108515989014190133483190455345808508477355
```

We now return to the closed form of $C(z)$:

```
sage: z = var('z')                                                             #␣
↪needs sage.symbolic
sage: C = s0; C                                                                #␣
↪needs sage.symbolic
-1/2*sqrt(-4*z + 1) + 1/2
```

The n-th coefficient in the Taylor series for $C(z)$ being given by $\frac{1}{n!}C(z)^{(n)}(0)$, we look at the successive derivatives $C(z)^{(n)}(z)$:

```
sage: derivative(C, z, 1)                                                    #␣
↪needs sage.symbolic
1/sqrt(-4*z + 1)
sage: derivative(C, z, 2)                                                    #␣
↪needs sage.symbolic
2/(-4*z + 1)^(3/2)
sage: derivative(C, z, 3)                                                    #␣
↪needs sage.symbolic
12/(-4*z + 1)^(5/2)
```

This suggests the existence of a simple explicit formula, which we will now seek. The following small function returns $d_n = n!\,c_n$:

```
sage: def d(n): return derivative(s0, n).subs(z=0)
```

Taking successive quotients:

```
sage: [ (d(n+1) / d(n)) for n in range(1,17) ]                               #␣
↪needs sage.symbolic
[2, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62]
```

we observe that d_n satisfies the recurrence relation $d_{n+1} = (4n-2)d_n$, from which we deduce that c_n satisfies the recurrence relation $c_{n+1} = \frac{(4n-2)}{n+1}c_n$. Simplifying, we find that c_n is the $(n-1)$-th Catalan number:

$$c_n = \text{Catalan}(n-1) = \frac{1}{n}\binom{2(n-1)}{n-1}.$$

We check this:

```
sage: n = var('n')                                                           #␣
↪needs sage.symbolic
sage: c = 1/n*binomial(2*(n-1),n-1)                                          #␣
↪needs sage.symbolic
sage: [c.subs(n=k) for k in range(1, 11)]                                    #␣
↪needs sage.symbolic
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
sage: [catalan_number(k-1) for k in range(1, 11)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

We can now calculate coefficients much further; here we calculate c_{100000} which has more than 60000 digits:

```
sage: cc = c(n=100000)                                                       #␣
↪needs sage.symbolic
```

This takes a couple of seconds:

```
sage: %time cc = c(100000)                  # not tested                     #␣
↪needs sage.symbolic
CPU times: user 2.34 s, sys: 0.00 s, total: 2.34 s
Wall time: 2.34 s
sage: ZZ(cc).ndigits()                                                       #␣
↪needs sage.symbolic
60198
```

The methods which we have used generalize to all recursively defined objects: the system of set-theoretic equations can be translated into a system of equations on the generating function, which enables the recursive calculation of its coefficients. If the set-theoretic equations are simple enough (for example, if they only involve Cartesian products and disjoint unions), the equation for $C(z)$ is algebraic. This equation has, in general, no closed-form solution. However, using *confinement*, one can deduce a *linear* differential equation which $C(z)$ satisfies. This differential equation, in turn, can be translated into a recurrence relation of fixed length on its coefficients c_n. In this case, the series is called *D-finite*. After the initial calculation of this recurrence relation, the calculation of coefficients is very fast. All these steps are purely algorithmic, and it is planned to port into `Sage` the implementations which exist in `Maple` (the `gfun` and `combstruct` packages) or `MuPAD-Combinat` (the `decomposableObjects` library).

For the moment, we illustrate this general procedure in the case of complete binary trees. The generating function $C(z)$ is a solution to an algebraic equation $P(z, C(z)) = 0$, where $P = P(x, y)$ is a polynomial with coefficients in $\mathbf{Q}$. In the present case, $P = y^2 - y + x$. We formally differentiate this equation with respect to z:

```
sage: # needs sage.symbolic
sage: x, y, z = var('x, y, z')
sage: P = function('P')(x, y)
sage: C = function('C')(z)
sage: equation =  P(x=z, y=C) == 0
sage: diff(equation, z)
diff(C(z), z)*D[1](P)(z, C(z)) + D[0](P)(z, C(z)) == 0
```

or, in a more readable format,

$$\frac{dC(z)}{dz}\frac{\partial P}{\partial y}(z, C(z)) + \frac{\partial P}{\partial x}(z, C(z)) = 0$$

From this we deduce:

$$\frac{dC(z)}{dz} = -\frac{\frac{\partial P}{\partial x}}{\frac{\partial P}{\partial y}}(z, C(z))\,.$$

In the case of complete binary trees, this gives:

```
sage: P = y^2 - y + x                                                       #␣
↪needs sage.symbolic
sage: Px = diff(P, x); Py = diff(P, y)                                      #␣
↪needs sage.symbolic
sage: - Px / Py                                                             #␣
↪needs sage.symbolic
-1/(2*y - 1)
```

Recall that $P(z, C(z)) = 0$. Thus, we can calculate this fraction mod P and, in this way, express the derivative of $C(z)$ as a *polynomial in* $C(z)$ *with coefficients in* $\mathbf{Q}(z)$. In order to achieve this, we construct the quotient ring $R = \mathbf{Q}(x)[y]/(P)$:

```
sage: Qx = QQ['x'].fraction_field()
sage: Qxy = Qx['y']
sage: R = Qxy.quo(P); R                                                     #␣
↪needs sage.symbolic
Univariate Quotient Polynomial Ring in ybar
over Fraction Field of Univariate Polynomial Ring in x
over Rational Field with modulus y^2 - y + x
```

Note: `ybar` is the name of the variable y in the quotient ring.

Todo: add link to some tutorial on quotient rings

We continue the calculation of this fraction in R:

```
sage: fraction = - R(Px) / R(Py); fraction                                    #␣
↪needs sage.symbolic
(1/2/(x - 1/4))*ybar - 1/4/(x - 1/4)
```

Note: The following variant does not work yet:

```
sage: fraction = R( - Px / Py ); fraction   # todo: not implemented
Traceback (most recent call last):
...
TypeError: denominator must be a unit
```

We lift the result to $\mathbf{Q}(x)[y]$ and then substitute z and $C(z)$ to obtain an expression for $\frac{d}{dz}C(z)$:

```
sage: fraction = fraction.lift(); fraction                                    #␣
↪needs sage.symbolic
(1/2/(x - 1/4))*y - 1/4/(x - 1/4)
sage: fraction(x=z, y=C)                                                      #␣
↪needs sage.symbolic
2*C(z)/(4*z - 1) - 1/(4*z - 1)
```

or, more legibly,

$$\frac{\partial C(z)}{\partial z} = \frac{1}{1-4z} - \frac{2}{1-4z}C(z)\,.$$

In this simple case, we can directly deduce from this expression a linear differential equation with coefficients in $\mathbf{Q}[z]$:

```
sage: # needs sage.symbolic
sage: equadiff = diff(C,z) == fraction(x=z, y=C)
sage: equadiff
diff(C(z), z) == 2*C(z)/(4*z - 1) - 1/(4*z - 1)
sage: equadiff = equadiff.simplify_rational()
sage: equadiff = equadiff * equadiff.rhs().denominator()
sage: equadiff = equadiff - equadiff.rhs()
sage: equadiff
(4*z - 1)*diff(C(z), z) - 2*C(z) + 1 == 0
```

or, more legibly,

$$(1-4z)\frac{\partial C(z)}{\partial z} + 2C(z) - 1 = 0\,.$$

It is trivial to verify this equation on the closed form:

```
sage: Cf = sage.symbolic.function_factory.function('C')                       #␣
↪needs sage.symbolic
sage: equadiff.substitute_function(Cf, s0.function(z))                        #␣
↪needs sage.symbolic
(4*z - 1)/sqrt(-4*z + 1) + sqrt(-4*z + 1) == 0
sage: bool(equadiff.substitute_function(Cf, s0.function(z)))                  #␣
↪needs sage.symbolic
True
```

In the general case, one continues to calculate successive derivatives of $C(z)$. These derivatives are *confined* in the quotient ring $\mathbf{Q}(z)[C]/(P)$ which is of finite dimension $\deg P$ over $\mathbf{Q}(z)$. Therefore, one will eventually find a linear relation among the first $\deg P$ derivatives of $C(z)$. Putting it over a single denominator, we obtain a linear differential

equation of degree $\leq \deg P$ with coefficients in $\mathbf{Q}[z]$. By extracting the coefficient of z^n in the differential equation, we obtain the desired recurrence relation on the coefficients; in this case we recover the relation we had already found, based on the closed form:

$$c_{n+1} = \frac{(4n-2)}{n+1} c_n$$

After fixing the correct initial conditions, it becomes possible to calculate the coefficients of $C(z)$ recursively:

```
sage: def C(n): return 1 if n <= 1 else (4*n-6)/n * C(n-1)
sage: [ C(i) for i in range(10) ]
[1, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
```

If n is too large for the explicit calculation of c_n, a sequence asymptotically equivalent to the sequence of coefficients c_n may be sought. Here again, there are generic techniques. The central tool is complex analysis, specifically, the study of the generating function around its singularities. In the present instance, the singularity is at $z_0 = 1/4$ and one would obtain $c_n \sim \frac{4^n}{n^{3/2}\sqrt{\pi}}$.

Summary

We see here a general phenomenon of computer algebra: the best *data structure* to describe a complicated mathematical object (a real number, a sequence, a formal power series, a function, a set) is often an equation defining the object (or a system of equations, typically with some initial conditions). Attempting to find a closed-form solution to this equation is not necessarily of interest: on the one hand, such a closed form rarely exists (e.g., the problem of solving a polynomial by radicals), and on the other hand, the equation, in itself, contains all the necessary information to calculate algorithmically the properties of the object under consideration (e.g., a numerical approximation, the initial terms or elements, an asymptotic equivalent), or to calculate with the object itself (e.g., performing arithmetic on power series). Therefore, instead of solving the equation, we look for the equation describing the object which is best suited to the problem we want to solve.

As we saw in our example, confinement (for example, in a finite dimensional vector space) is a fundamental tool for studying such equations. This notion of confinement is widely applicable in elimination techniques (linear algebra, Gröbner bases, and their algebro-differential generalizations). The same tool is central in algorithms for automatic summation and automatic verification of identities (Gosper's algorithm, Zeilberger's algorithm, and their generalizations; see also *Exercise: alternating sign matrices*).

Todo: add link to some tutorial on summation

All these techniques and their many generalizations are at the heart of very active topics of research: automatic combinatorics and analytic combinatorics, with major applications in the analysis of algorithms. It is likely, and desirable, that they will be progressively implemented in `Sage`.

Common enumerated sets

First example: the subsets of a set

Fix a set E of size n and consider the subsets of E of size k. We know that these subsets are counted by the binomial coefficients $\binom{n}{k}$. We can therefore calculate the number of subsets of size $k = 2$ of $E = \{1, 2, 3, 4\}$ with the function `binomial`:

```
sage: binomial(4, 2)
6
```

Alternatively, we can *construct* the set $\mathcal{P}_2(E)$ of all the subsets of size 2 of E, then ask its cardinality:

```
sage: S = Subsets([1,2,3,4], 2)
sage: S.cardinality()
6
```

Once S has been constructed, we can also obtain the list of its elements:

```
sage: S.list()
[{1, 2}, {1, 3}, {1, 4}, {2, 3}, {2, 4}, {3, 4}]
```

or select an element at random:

```
sage: S.random_element()                # random
{1, 4}
```

More precisely, the object S models the set $\mathcal{P}_2(E)$ equipped with a fixed order (here, lexicographic order). It is therefore possible to ask for its 5-th element, keeping in mind that, as with Python lists, the first element is numbered zero:

```
sage: S.unrank(4)
{2, 4}
```

As a shortcut, in this setting, one can also use the notation:

```
sage: S[4]
{2, 4}
```

but this should be used with care because some sets have a natural indexing other than by $(0, 1, \dots)$.

Conversely, one can calculate the position of an object in this order:

```
sage: s = S([2,4]); s
{2, 4}
sage: S.rank(s)
4
```

Note that S is *not* the list of its elements. One can, for example, model the set $\mathcal{P}(\mathcal{P}(\mathcal{P}(E)))$ and calculate its cardinality ($2^{2^{2^4}}$):

```
sage: E = Set([1,2,3,4])
sage: S = Subsets(Subsets(Subsets(E))); S
Subsets of Subsets of Subsets of {1, 2, 3, 4}
sage: n = S.cardinality(); n
200352993040684646497907235156025575044782547556975141926501697 3...
```

which is roughly $2 \cdot 10^{19728}$:

```
sage: n.ndigits()
19729
```

or ask for its 237102124-th element:

```
sage: S.unrank(237102123) # random print output
{{{2, 4}, {1, 4}, {}, {1, 3, 4}, {1, 2, 4}, {4}, {2, 3}, {1, 3}, {2}},
  {{1, 3}, {2, 4}, {1, 2, 4}, {}, {3, 4}}}
```

It would be physically impossible to construct explicitly all the elements of S, as there are many more of them than there are particles in the universe (estimated at 10^{82}).

Remark: it would be natural in Python to use len(S) to ask for the cardinality of S. This is not possible because Python requires that the result of len be an integer of type int; this could cause overflows, and would not permit the return of {Infinity} for infinite sets:

```
sage: len(S)
Traceback (most recent call last):
...
OverflowError: cannot fit 'int' into an index-sized integer
```

Partitions of integers

We now consider another classic problem: given a positive integer n, in how many ways can it be written in the form of a sum $n = i_1 + i_2 + \cdots + i_\ell$, where $i_1, \ldots, i_\ell$ are positive integers? There are two cases to distinguish:

- the order of the elements in the sum is not important, in which case we call $(i_1, \ldots, i_\ell)$ a *partition* of n;
- the order of the elements in the sum is important, in which case we call $(i_1, \ldots, i_\ell)$ a *composition* of n.

We will begin with the partitions of $n = 5$; as before, we begin by constructing the set of these partitions:

```
sage: P5 = Partitions(5); P5
Partitions of the integer 5
```

then we ask for its cardinality:

```
sage: P5.cardinality()
7
```

We look at these 7 partitions; the order being irrelevant, the entries are ordered, by convention, in decreasing order.

```
sage: P5.list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1],
 [1, 1, 1, 1, 1]]
```

The calculation of the number of partitions uses the Rademacher formula (Wikipedia article Partition_(number_theory)), implemented in C and highly optimized, which makes it very fast:

```
sage: Partitions(100000).cardinality()
2749351056977569651267751632098635268817342931598005475820312598430214732811496417305505074166073662
```

Partitions of integers are combinatorial objects naturally equipped with many operations. They are therefore returned as objects that are richer than simple lists:

```
sage: P7 = Partitions(7)
sage: p = P7.unrank(5); p
[4, 2, 1]
sage: type(p)
<class 'sage.combinat.partition.Partitions_n_with_category.element_class'>
```

For example, they can be represented graphically by a Ferrers diagram:

```
sage: print(p.ferrers_diagram())
****
**
*
```

We leave it to the user to explore by introspection the available operations.

Note that we can also construct a partition directly by:

```
sage: Partition([4,2,1])
[4, 2, 1]
```

or:

```
sage: P7([4,2,1])
[4, 2, 1]
```

If one wants to restrict the possible values of the parts $i_1, \ldots, i_\ell$ of the partition as, for example, when giving change, one can use `WeightedIntegerVectors`. For example, the following calculation:

```
sage: WeightedIntegerVectors(8, [2,3,5]).list()
[[0, 1, 1], [1, 2, 0], [4, 0, 0]]
```

shows that to make 8 dollars using 2, 3, and 5 dollar bills, one can use a 3 and a 5 dollar bill, or a 2 and two 3 dollar bills, or four 2 dollar bills.

Compositions of integers are manipulated the same way:

```
sage: C5 = Compositions(5); C5
Compositions of 5
sage: C5.cardinality()
16
sage: C5.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 2, 1], [1, 1, 3],
 [1, 2, 1, 1], [1, 2, 2], [1, 3, 1], [1, 4], [2, 1, 1, 1],
 [2, 1, 2], [2, 2, 1], [2, 3], [3, 1, 1], [3, 2], [4, 1], [5]]
```

The number 16 above seems significant and suggests the existence of a formula. We look at the number of compositions of n ranging from 0 to 9:

```
sage: [Compositions(n).cardinality() for n in range(10)]
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256]
```

Similarly, if we consider the number of compositions of 5 by length, we find a line of Pascal's triangle:

```
sage: x = var('x')                                                          #␣
↪needs sage.symbolic
sage: sum(x^len(c) for c in C5)                                             #␣
↪needs sage.symbolic
x^5 + 4*x^4 + 6*x^3 + 4*x^2 + x
```

The above example uses a functionality which we have not seen yet: `C5` being iterable, it can be used like a list in a `for` loop or a comprehension (*Set comprehension and iterators*).

> Prove the formulas suggested by the above examples for the number of compositions of n and the number of compositions of n of length k; investigate by introspection whether `Sage` uses these formulas for calculating cardinalities.

Some other finite enumerated sets

Essentially, the principle is the same for all the finite sets with which one wants to do combinatorics in Sage; begin by constructing an object which models this set, and then supply appropriate methods, following a uniform interface[1]. We now give a few more typical examples.

Intervals of integers:

```
sage: C = IntegerRange(3, 21, 2); C
{3, 5, ..., 19}
sage: C.cardinality()
9
sage: C.list()
[3, 5, 7, 9, 11, 13, 15, 17, 19]
```

Permutations:

```
sage: C = Permutations(4); C
Standard permutations of 4
sage: C.cardinality()
24
sage: C.list()
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 3, 2, 4], [1, 3, 4, 2],
 [1, 4, 2, 3], [1, 4, 3, 2], [2, 1, 3, 4], [2, 1, 4, 3],
 [2, 3, 1, 4], [2, 3, 4, 1], [2, 4, 1, 3], [2, 4, 3, 1],
 [3, 1, 2, 4], [3, 1, 4, 2], [3, 2, 1, 4], [3, 2, 4, 1],
 [3, 4, 1, 2], [3, 4, 2, 1], [4, 1, 2, 3], [4, 1, 3, 2],
 [4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 1, 2], [4, 3, 2, 1]]
```

Set partitions:

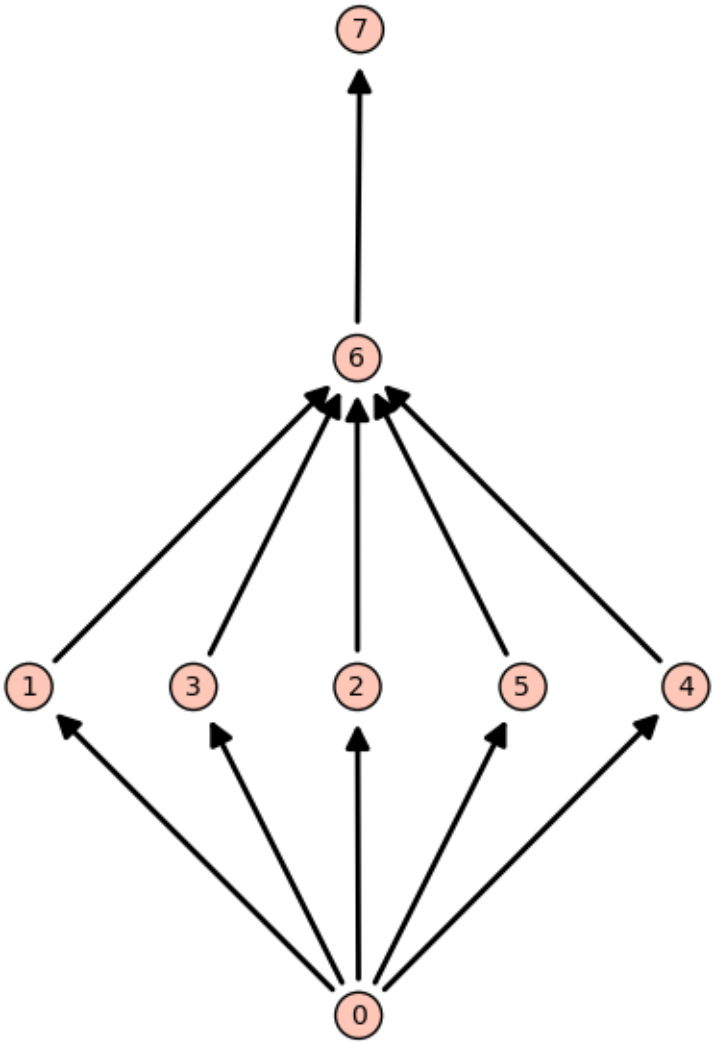
```
sage: C = SetPartitions(["a", "b", "c"])
sage: C # random print output
Set partitions of {'a', 'c', 'b'}
sage: C.cardinality()
5
sage: C.list()
[{{'a', 'b', 'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'c'}, {'b'}},
 {{'a'}, {'b', 'c'}},
 {{'a'}, {'b'}, {'c'}}]
```

Partial orders on a set of 8 elements, up to isomorphism:

```
sage: C = Posets(8); C
Posets containing 8 elements
sage: C.cardinality()
16999
```

```
sage: C.unrank(20).plot()
Graphics object consisting of 20 graphics primitives
```

[1] Or at least that should be the case; there are still many corners to clean up.

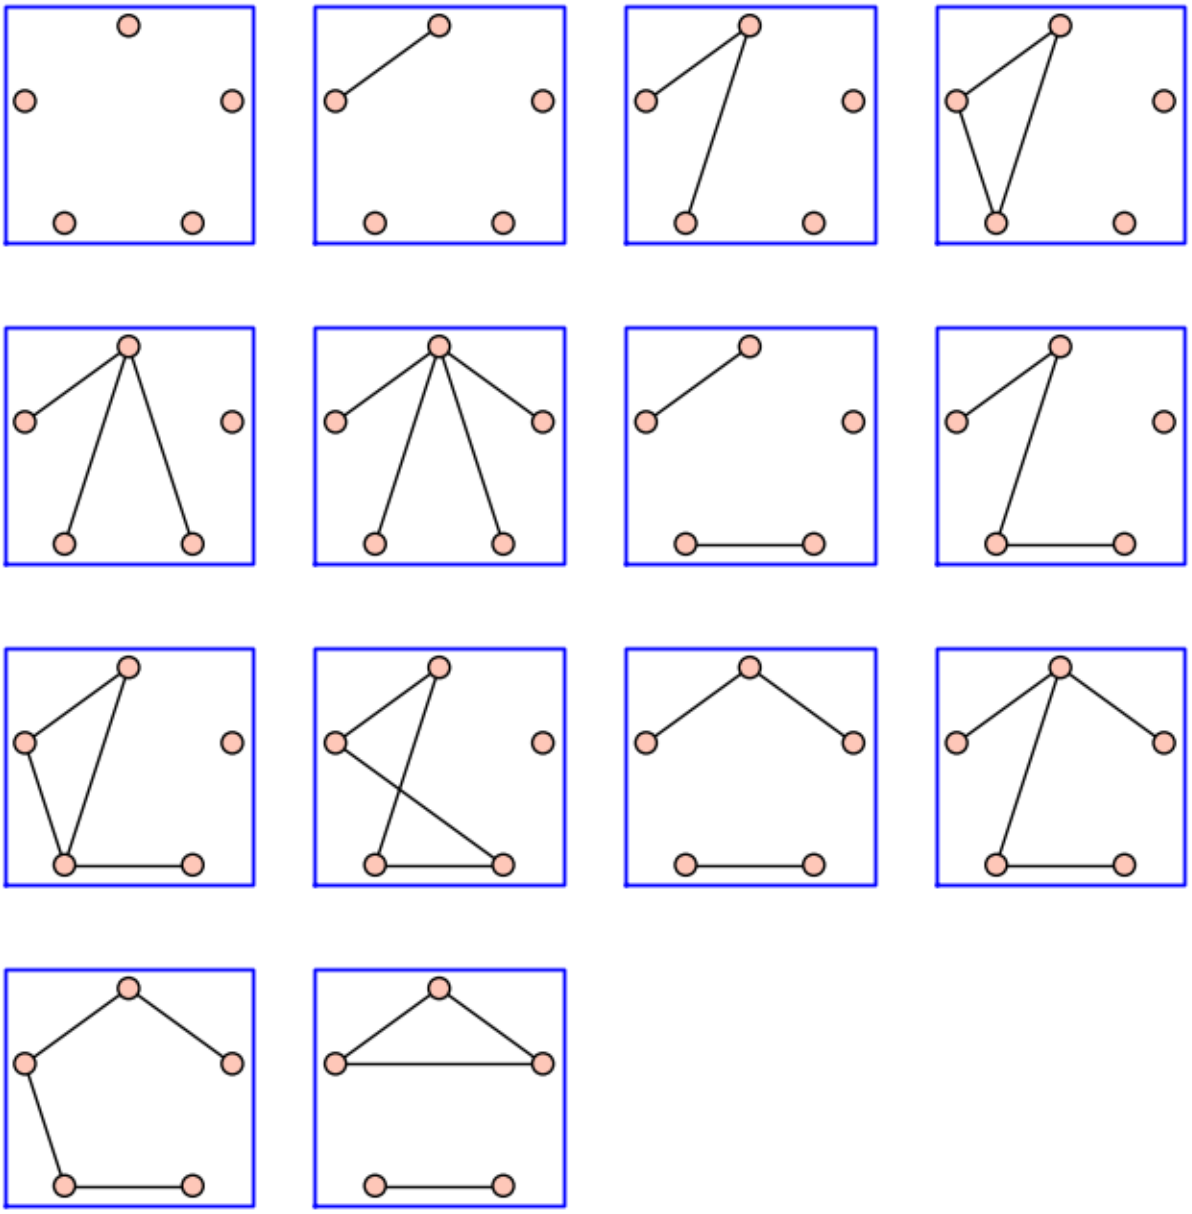


One can iterate through all graphs up to isomorphism. For example, there are 34 simple graphs with 5 vertices:

```
sage: len(list(graphs(5)))
34
```

Here are those with at most 4 edges:

```
sage: up_to_four_edges = list(graphs(5, lambda G: G.size() <= 4))
sage: pretty_print(*up_to_four_edges)
```



However, the *set* `C` of these graphs is not yet available in `Sage`; as a result, the following commands are not yet implemented:

```
sage: # not implemented
sage: C = Graphs(5)
sage: C.cardinality()
34
sage: Graphs(19).cardinality()
246378092531250045243830074914327 68
sage: Graphs(19).random_element()
Graph on 19 vertices
```

What we have seen so far also applies, in principle, to finite algebraic structures like the dihedral groups:

```
sage: G = DihedralGroup(4); G
Dihedral group of order 8 as a permutation group
sage: G.cardinality()
8
sage: G.list()
[(), (1,3)(2,4), (1,4,3,2), (1,2,3,4), (2,4), (1,3), (1,4)(2,3), (1,2)(3,4)]
```

or the algebra of 2×2 matrices over the finite field $\mathbf{Z}/2\mathbf{Z}$:

```
sage: C = MatrixSpace(GF(2), 2)                                                 #␣
↪needs sage.modules sage.rings.finite_rings
sage: C.list()                                                                  #␣
↪needs sage.modules sage.rings.finite_rings
[
[0 0]  [1 0]  [0 1]  [0 0]  [0 0]  [1 1]  [1 0]  [1 0]  [0 1]  [0 1]
[0 0], [0 0], [0 0], [1 0], [0 1], [0 0], [1 0], [0 1], [1 0], [0 1],

[0 0]  [1 1]  [1 1]  [1 0]  [0 1]  [1 1]
[1 1], [1 0], [0 1], [1 1], [1 1], [1 1]
]
sage: C.cardinality()                                                           #␣
↪needs sage.modules sage.rings.finite_rings
16
```

Exercise

List all the monomials of degree 5 in three variables (see `IntegerVectors`). Manipulate the ordered set partitions `OrderedSetPartitions` and standard tableaux (`StandardTableaux`).

Exercise

List the alternating sign matrices of size 3, 4, and 5 (`AlternatingSignMatrices`), and try to guess the definition. The discovery and proof of the formula for the enumeration of these matrices (see the method `cardinality`), motivated by calculations of determinants in physics, is quite a story. In particular, the first proof, given by Zeilberger in 1992 was automatically produced by a computer program. It was 84 pages long, and required nearly a hundred people to verify it.

Exercise

Calculate by hand the number of vectors in $(\mathbf{Z}/2\mathbf{Z})^5$, and the number of matrices in $GL_3(\mathbf{Z}/2\mathbf{Z})$ (that is to say, the number of invertible 3×3 matrices with coefficients in $\mathbf{Z}/2\mathbf{Z}$). Verify your answer with `Sage`. Generalize to $GL_n(\mathbf{Z}/q\mathbf{Z})$.

Set comprehension and iterators

We will now show some of the possibilities offered by `Python` for constructing (and iterating through) sets, with a notation that is flexible and close to usual mathematical usage, and in particular the benefits this yields in combinatorics.

We begin by constructing the finite set $\{i^2 \parallel i \in \{1, 3, 7\}\}$:

```
sage: [ i^2 for i in [1, 3, 7] ]
[1, 9, 49]
```

and then the same set, but with i running from 1 to 9:

```
sage: [ i^2 for i in range(1,10) ]
[1, 4, 9, 16, 25, 36, 49, 64, 81]
```

A construction of this form in `Python` is called *set comprehension*. A clause can be added to keep only those elements with i prime:

```
sage: [ i^2 for i in range(1,10) if is_prime(i) ]
[4, 9, 25, 49]
```

Combining more than one set comprehension, it is possible to construct the set $\{(i, j) \mid 1 \leq j < i < 5\}$:

```
sage: [ (i,j) for i in range(1,6) for j in range(1,i) ]
[(2, 1), (3, 1), (3, 2), (4, 1), (4, 2), (4, 3),
 (5, 1), (5, 2), (5, 3), (5, 4)]
```

or to produce Pascal's triangle:

```
sage: [[binomial(n,i) for i in range(n+1)] for n in range(10)]
[[1],
 [1, 1],
 [1, 2, 1],
 [1, 3, 3, 1],
 [1, 4, 6, 4, 1],
 [1, 5, 10, 10, 5, 1],
 [1, 6, 15, 20, 15, 6, 1],
 [1, 7, 21, 35, 35, 21, 7, 1],
 [1, 8, 28, 56, 70, 56, 28, 8, 1],
 [1, 9, 36, 84, 126, 126, 84, 36, 9, 1]]
```

The execution of a set comprehension is accomplished in two steps; first an *iterator* is constructed, and then a list is filled with the elements successively produced by the iterator. Technically, an *iterator* is an object with a method `next` which returns a new value each time it is called, until it is exhausted. For example, the following iterator `it`:

```
sage: it = (binomial(3, i) for i in range(4))
```

returns successively the binomial coefficients $\binom{3}{i}$ with $i = 0, 1, 2, 3$:

```
sage: next(it)
1
sage: next(it)
3
sage: next(it)
3
sage: next(it)
1
```

When the iterator is finally exhausted, an exception is raised:

```
sage: next(it)
Traceback (most recent call last):
  ...
StopIteration
```

More generally, an *iterable* is a Python object L (a list, a set, ...) over whose elements it is possible to iterate. Technically, the iterator is constructed by iter(L). In practice, the commands iter and next are used very rarely, since for loops and list comprehensions provide a much pleasanter syntax:

```
sage: for s in Subsets(3):
....:     print(s)
{}
{1}
{2}
{3}
{1, 2}
{1, 3}
{2, 3}
{1, 2, 3}
```

```
sage: [ s.cardinality() for s in Subsets(3) ]
[0, 1, 1, 1, 2, 2, 2, 3]
```

What is the point of an iterator? Consider the following example:

```
sage: sum( [ binomial(8, i) for i in range(9) ] )
256
```

When it is executed, a list of 9 elements is constructed, and then it is passed as an argument to sum to add them up. If, on the other hand, the iterator is passed directly to sum (note the absence of square brackets):

```
sage: sum( binomial(8, i) for i in range(9) )
256
```

the function sum receives the iterator directly, and can short-circuit the construction of the intermediate list. If there are a large number of elements, this avoids allocating a large quantity of memory to fill a list which will be immediately destroyed.

Most functions that take a list of elements as input will also accept an iterator (or an iterable) instead. To begin with, one can obtain the list (or the tuple) of elements of an iterator as follows:

```
sage: list(binomial(8, i) for i in range(9))
[1, 8, 28, 56, 70, 56, 28, 8, 1]
sage: tuple(binomial(8, i) for i in range(9))
(1, 8, 28, 56, 70, 56, 28, 8, 1)
```

We now consider the functions all and any which denote respectively the n-ary *and* and *or*:

```
sage: all([True, True, True, True])
True
sage: all([True, False, True, True])
False
sage: any([False, False, False, False])
False
sage: any([False, False, True, False])
True
```

The following example verifies that all primes from 3 to 99 are odd:

```
sage: all( is_odd(p) for p in range(3,100) if is_prime(p) )
True
```

A *Mersenne prime* is a prime of the form $2^p - 1$. We verify that, for $p < 1000$, if $2^p - 1$ is prime, then p is also prime:

```
sage: def mersenne(p): return 2^p -1
sage: [ is_prime(p)
....:   for p in range(1000) if is_prime(mersenne(p)) ]
[True, True, True, True, True, True, True, True, True, True,
 True, True, True, True]
```

Is the converse true?

Exercise

Try the two following commands and explain the considerable difference in the length of the calculations:

```
sage: all(   is_prime(mersenne(p))
....:        for p in range(1000) if is_prime(p)  )
False
sage: all( [ is_prime(mersenne(p))
....:        for p in range(1000) if is_prime(p)] )
False
```

We now try to find the smallest counter-example. In order to do this, we use the `Sage` function `exists`:

```
sage: exists( (p for p in range(1000) if is_prime(p)),
....:         lambda p: not is_prime(mersenne(p)) )
(True, 11)
```

Alternatively, we could construct an iterator on the counter-examples:

```
sage: counter_examples = (p for p in range(1000)
....:      if is_prime(p) and not is_prime(mersenne(p)))
sage: next(counter_examples)
11
sage: next(counter_examples)
23
```

Exercise

What do the following commands do?

```
sage: cubes = [t**3 for t in range(-999,1000)]
sage: exists([(x,y) for x in cubes for y in cubes],  # long time (3s, 2012)
....:        lambda x_y: x_y[0] + x_y[1] == 218)
(True, (-125, 343))
sage: exists(((x,y) for x in cubes for y in cubes),  # long time (2s, 2012)
....:        lambda x_y: x_y[0] + x_y[1] == 218)
(True, (-125, 343))
```

Which of the last two is more economical in terms of time? In terms of memory? By how much?

Exercise

Try each of the following commands, and explain its result. If possible, hide the result first and try to guess it before launching the command.

Todo: hide the results by default

Warning: it will be necessary to interrupt the execution of some of the commands

```
sage: x = var('x')                                                          #␣
↪needs sage.symbolic
sage: sum(x^len(s) for s in Subsets(8))                                     #␣
↪needs sage.symbolic
x^8 + 8*x^7 + 28*x^6 + 56*x^5 + 70*x^4 + 56*x^3 + 28*x^2 + 8*x + 1
```

```
sage: sum(x^p.length() for p in Permutations(3))                            #␣
↪needs sage.symbolic
x^3 + 2*x^2 + 2*x + 1
```

```
sage: factor(sum(x^p.length() for p in Permutations(3)))                    #␣
↪needs sage.symbolic
(x^2 + x + 1)*(x + 1)
```

```
sage: P = Permutations(5)
sage: all(p in P for p in P)
True
```

```
sage: for p in GL(2, 2): print(p); print("")
[1 0]
[0 1]

[0 1]
[1 0]

[0 1]
[1 1]

[1 1]
[0 1]

[1 1]
[1 0]

[1 0]
[1 1]
```

```
sage: for p in Partitions(3): print(p)    # not tested
[3]
[2, 1]
[1, 1, 1]
...
```

```
sage: for p in Partitions(): print(p)     # not tested
[]
[1]
[2]
[1, 1]
[3]
...
```

```
sage: for p in Primes(): print(p)         # not tested
2
3
5
7
...
```

```
sage: exists( Primes(), lambda p: not is_prime(mersenne(p)) )
(True, 11)
```

```
sage: counter_examples = (p for p in Primes()
....:                     if not is_prime(mersenne(p)))
sage: for p in counter_examples: print(p)    # not tested
11
23
29
37
41
43
47
...
```

Operations on iterators

Python provides numerous tools for manipulating iterators; most of them are in the itertools library, which can be imported by:

```
sage: import itertools
```

We will demonstrate some applications, taking as a starting point the permutations of 3:

```
sage: list(Permutations(3))
[[1, 2, 3], [1, 3, 2], [2, 1, 3],
 [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

We can list the elements of a set by numbering them:

```
sage: list(enumerate(Permutations(3)))
[(0, [1, 2, 3]), (1, [1, 3, 2]), (2, [2, 1, 3]),
 (3, [2, 3, 1]), (4, [3, 1, 2]), (5, [3, 2, 1])]
```

or select only the elements in positions 2, 3, and 4 (analogue of l[1:4]):

```
sage: import itertools
sage: list(itertools.islice(Permutations(3), int(1), int(4)))
[[1, 3, 2], [2, 1, 3], [2, 3, 1]]
```

To apply a function to all the elements, one can do:

```
sage: [z.cycle_type() for z in Permutations(3)]
[[1, 1, 1], [2, 1], [2, 1], [3], [3], [2, 1]]
```

and similarly to select the elements satisfying a certain condition:

```
sage: [z for z in Permutations(3) if z.has_pattern([1,2])]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

Implementation of new iterators

It is easy to construct new iterators, using the keyword `yield` instead of `return` in a function:

```
sage: def f(n):
....:     for i in range(n):
....:         yield i
```

After the `yield`, execution is not halted, but only suspended, ready to be continued from the same point. The result of the function is therefore an iterator over the successive values returned by `yield`:

```
sage: g = f(4)
sage: next(g)
0
sage: next(g)
1
sage: next(g)
2
sage: next(g)
3
```

```
sage: next(g)
Traceback (most recent call last):
  ...
StopIteration
```

The function could be used as follows:

```
sage: [ x for x in f(5) ]
[0, 1, 2, 3, 4]
```

This model of computation, called *continuation*, is very useful in combinatorics, especially when combined with recursion. Here is how to generate all words of a given length on a given alphabet:

```
sage: def words(alphabet,l):
....:     if l == 0:
....:         yield []
....:     else:
....:         for word in words(alphabet, l-1):
....:             for l in alphabet:
....:                 yield word + [l]
sage: [ w for w in words(['a','b'], 3) ]
[['a', 'a', 'a'], ['a', 'a', 'b'], ['a', 'b', 'a'],
 ['a', 'b', 'b'], ['b', 'a', 'a'], ['b', 'a', 'b'],
 ['b', 'b', 'a'], ['b', 'b', 'b']]
```

These words can then be counted by:

```
sage: sum(1 for w in words(['a','b','c','d'], 10))
1048576
```

Counting the words one by one is clearly not an efficient method in this case, since the formula n^ℓ is also available; note, though, that this is not the stupidest possible approach - it does, at least, avoid constructing the entire list in memory.

We now consider Dyck words, which are well-parenthesized words in the letters "(" and ")". The function below generates all the Dyck words of a given length (where the length is the number of pairs of parentheses), using the recursive definition which says that a Dyck word is either empty or of the form $(w_1)w_2$ where w_1 and w_2 are Dyck words:

```
sage: def dyck_words(l):
....:     if l==0:
....:         yield ''
....:     else:
....:         for k in range(l):
....:             for w1 in dyck_words(k):
....:                 for w2 in dyck_words(l-k-1):
....:                     yield '('+w1+')'+w2
```

Here are all the Dyck words of length 4:

```
sage: list(dyck_words(4))
['()()()()', '()()(())', '()(())()', '()(()())', '()((()))',
 '(())()()', '(())(())', '(()())()', '((()))()', '(()()())',
 '(()(()))', '((())())', '((()()))', '(((())))']
```

Counting them, we recover a well-known sequence:

```
sage: [ sum(1 for w in dyck_words(l)) for l in range(10) ]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

Exercise: complete binary tree iterator

Construct an iterator on the set C_n of complete binary trees with n leaves (see *Enumeration of trees using generating functions*).

Hint: Sage 4.8.2 does not yet have a native data structure to represent complete binary trees. One simple way to represent them is to define a formal variable Leaf for the leaves and a formal 2-ary function Node:

```
sage: var('Leaf')                                                        #␣
↪needs sage.symbolic
Leaf
sage: function('Node', nargs=2)                                          #␣
↪needs sage.symbolic
Node
```

The second tree in *Figure: The five complete binary trees with four leaves* can be represented by the expression:

```
sage: tr = Node(Node(Leaf, Node(Leaf, Leaf)), Leaf)                      #␣
↪needs sage.symbolic
```

Constructions

We will now see how to construct new sets starting from these building blocks. In fact, we have already begun to do this with the construction of $\mathcal{P}(\mathcal{P}(\mathcal{P}(\{1,2,3,4\})))$ in the previous section, and to construct the example of sets of cards in *Initial examples*.

Consider a large Cartesian product:

```
sage: C = cartesian_product([Compositions(8), Permutations(20)]); C
The Cartesian product of (Compositions of 8, Standard permutations of 20)
sage: C.cardinality()
311411457046609920000
```

Clearly, it is impractical to construct the list of all the elements of this Cartesian product! And, in the following example, H is equipped with the usual combinatorial operations and also its structure as a product group:

```
sage: G = DihedralGroup(4)
sage: H = cartesian_product([G,G])
sage: H in Groups()
True
sage: H.an_element()
((1,3), (1,3))
sage: t = H([G.gen(0), G.gen(0)])
sage: t
((1,2,3,4), (1,2,3,4))
sage: t*t
((1,3)(2,4), (1,3)(2,4))
```

We now construct the union of two existing disjoint sets:

```
sage: C = DisjointUnionEnumeratedSets(
....:       [ Compositions(4), Permutations(3)] )
sage: C
Disjoint union of Family (Compositions of 4,
Standard permutations of 3)
sage: C.cardinality()
14
sage: C.list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2],
[3, 1], [4], [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1],
[3, 1, 2], [3, 2, 1]]
```

It is also possible to take the union of more than two disjoint sets, or even an infinite number of them. We will now construct the set of all permutations, viewed as the union of the sets P_n of permutations of size n. We begin by constructing the infinite family $F = (P_n)_{n \in N}$:

```
sage: F = Family(NonNegativeIntegers(), Permutations); F
Lazy family (<class 'sage.combinat.permutation.Permutations'>(i))_{i in Non negative␣
↪integers}
sage: F.keys()
Non negative integers
sage: F[1000]
Standard permutations of 1000
```

Now we can construct the disjoint union $\bigcup_{n \in \mathbf{N}} P_n$:

```
sage: U = DisjointUnionEnumeratedSets(F); U
Disjoint union of
```

(continues on next page)

(continued from previous page)

```
Lazy family (<class 'sage.combinat.permutation.Permutations'>(i))_{i in Non negative␣
↪integers}
```

It is an infinite set:

```
sage: U.cardinality()
+Infinity
```

which doesn't prohibit iteration through its elements, though it will be necessary to interrupt it at some point:

```
sage: for p in U:                # not tested
....:     print(p)
[]
[1]
[1, 2]
[2, 1]
[1, 2, 3]
[1, 3, 2]
[2, 1, 3]
[2, 3, 1]
[3, 1, 2]
...
```

Note: the above set could also have been constructed directly with:

```
sage: U = Permutations(); U
Standard permutations
```

Summary

Sage provides a library of common enumerated sets, which can be combined by standard constructions, giving a toolbox that is flexible (but which could still be expanded). It is also possible to add new building blocks to Sage with a few lines (see the code in `FiniteEnumeratedSets().example()`). This is made possible by the uniformity of the interfaces and the fact that Sage is based on an object-oriented language. Also, very large or even infinite sets can be manipulated thanks to lazy evaluation strategies (iterators, etc.).

There is no magic to any of this: under the hood, Sage applies the usual rules (for example, that the cardinality of $E \times E$ is $|E|^2$); the added value comes from the capacity to manipulate complicated constructions. The situation is comparable to Sage's implementation of differential calculus: Sage applies the usual rules for differentiation of functions and their compositions, where the added value comes from the possibility of manipulating complicated formulas. In this sense, Sage implements a *calculus* of finite enumerated sets.

Generic algorithms

Lexicographic generation of lists of integers

Among the classic enumerated sets, especially in algebraic combinatorics, a certain number are composed of lists of integers of fixed sum, such as partitions, compositions, or integer vectors. These examples can also have supplementary constraints added to them. Here are some examples. We start with the integer vectors with sum 10 and length 3, with parts bounded below by 2, 4 and 2 respectively:

```
sage: IntegerVectors(10, 3, min_part=2, max_part=5,
....:                inner=[2, 4, 2]).list()
[[4, 4, 2], [3, 5, 2], [3, 4, 3], [2, 5, 3], [2, 4, 4]]
```

The compositions of 5 with each part at most 3, and with length 2 or 3:

```
sage: Compositions(5, max_part=3,
....:              min_length=2, max_length=3).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [1, 3, 1],
 [1, 2, 2], [1, 1, 3]]
```

The strictly decreasing partitions of 5:

```
sage: Partitions(5, max_slope=-1).list()
[[5], [4, 1], [3, 2]]
```

These sets share the same underlying algorithmic structure, implemented in the more general (and slightly more cumbersome) class `IntegerListsLex`. This class models sets of vectors $(\ell_0, \ldots, \ell_k)$ of non-negative integers, with constraints on the sum and the length, and bounds on the parts and on the consecutive differences between the parts. Here are some more examples:

```
sage: IntegerListsLex(10, length=3,
....:                 min_part=2, max_part=5,
....:                 floor=[2, 4, 2]).list()
[[4, 4, 2], [3, 5, 2], [3, 4, 3], [2, 5, 3], [2, 4, 4]]

sage: IntegerListsLex(5, min_part=1, max_part=3,
....:                 min_length=2, max_length=3).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2],
 [1, 3, 1], [1, 2, 2], [1, 1, 3]]

sage: IntegerListsLex(5, min_part=1, max_slope=-1).list()
[[5], [4, 1], [3, 2]]

sage: list(Compositions(5, max_length=2))
[[5], [4, 1], [3, 2], [2, 3], [1, 4]]

sage: list(IntegerListsLex(5, max_length=2, min_part=1))
[[5], [4, 1], [3, 2], [2, 3], [1, 4]]
```

The point of the model of `IntegerListsLex` is in the compromise between generality and efficiency. The main algorithm permits iteration through the elements of such a set S in reverse lexicographic order with a good complexity in most practical use cases. Roughly speaking, the time needed to iterate through all the elements of S is proportional to the number of elements, where the proportion factor is controlled by the length l of the longest element of S. In addition, the memory usage is also controlled by l, which is to say negligible in practice.

This algorithm is based on a very general principle for traversing a decision tree, called *branch and bound*: at the top level, we run through all the possible choices for ℓ_0; for each of these choices, we run through all the possible choices for ℓ_1, and so on. Mathematically speaking, we have put the structure of a prefix tree on the elements of S: a node of the tree at depth k corresponds to a prefix $\ell_0, \ldots, \ell_k$ of one (or more) elements of S (see *Figure: The prefix tree of the partitions of 5.*).

The usual problem with this type of approach is to avoid bad decisions which lead to leaving the prefix tree and exploring dead branches; this is particularly problematic because the growth of the number of elements is usually exponential in the depth. It turns out that the constraints listed above are simple enough to be able to reasonably predict when a sequence $\ell_0, \ldots, \ell_k$ is a prefix of some element S. Hence, most dead branches can be pruned.

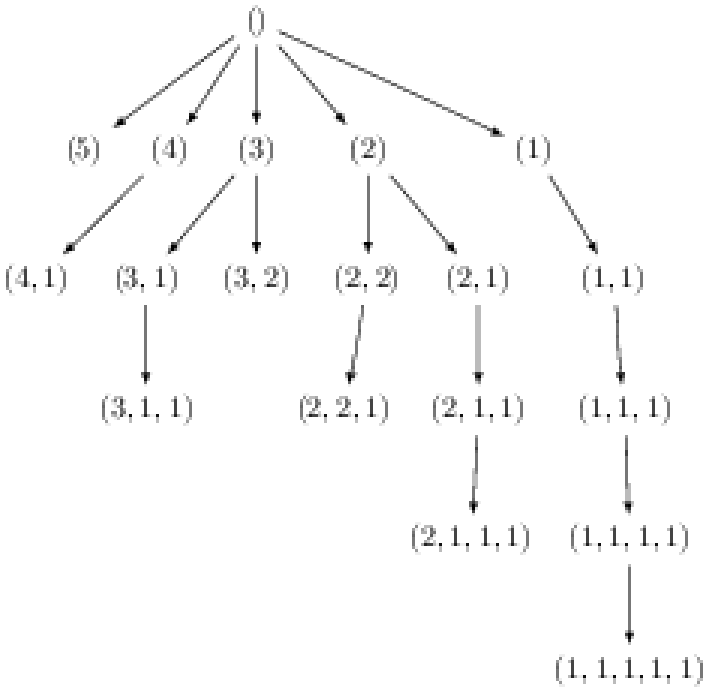


Fig. 2: Figure: The prefix tree of the partitions of 5.

Integer points in polytopes

Although the algorithm for iteration in `IntegerListsLex` is efficient, its counting algorithm is naive: it just iterates over all the elements.

There is an alternative approach to treating this problem: modelling the desired lists of integers as the set of integer points of a polytope, that is to say, the set of solutions with integer coordinates of a system of linear inequalities. This is a very general context in which there exist advanced counting algorithms (e.g. Barvinok), which are implemented in libraries like `LattE`. Iteration does not pose a hard problem in principle. However, there are two limitations that justify the existence of `IntegerListsLex`. The first is theoretical: lattice points in a polytope only allow modelling of problems of a fixed dimension (length). The second is practical: at the moment only the library `PALP` has a `Sage` interface, and though it offers multiple capabilities for the study of polytopes, in the present application it only produces a list of lattice points, without providing either an iterator or non-naive counting:

```
sage: A = random_matrix(ZZ, 6, 3, x=7)
sage: L = LatticePolytope(A.rows())
sage: L.points()                                    # random
M(4, 1, 0),
M(0, 3, 5),
M(2, 2, 3),
M(6, 1, 3),
M(1, 3, 6),
M(6, 2, 3),
M(3, 2, 4),
M(3, 2, 3),
M(4, 2, 4),
M(4, 2, 3),
M(5, 2, 3)
in 3-d lattice M
```

(continues on next page)

(continued from previous page)

```
sage: L.npoints()                                    # random
11
```

This polytope can be visualized in 3D with `L.plot3d()` (see *Figure: The polytope L and its integer points, in cross-eyed stereographic perspective.*).

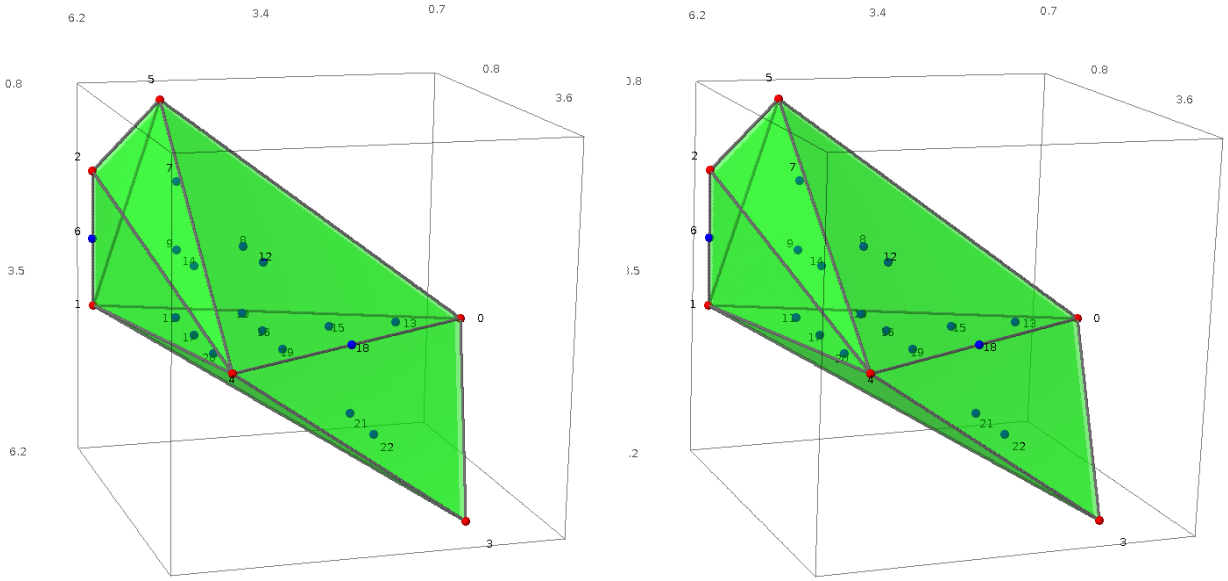

Fig. 3: Figure: The polytope L and its integer points, in cross-eyed stereographic perspective.

Species, decomposable combinatorial classes

In *Enumeration of trees using generating functions*, we showed how to use the recursive definition of binary trees to count them efficiently using generating functions. The techniques we used there are very general, and apply whenever the sets involved can be defined recursively (depending on who you ask, such a set is called a *decomposable combinatorial class* or, roughly speaking, a *combinatorial species*). This includes all the types of trees, but also permutations, compositions, functional graphs, etc.

Here, we illustrate just a few examples using the `Sage` library on combinatorial species:

```
sage: from sage.combinat.species.library import *
sage: o = var('o')                                                    #␣
↪needs sage.symbolic
```

We begin by redefining the complete binary trees; to do so, we stipulate the recurrence relation directly on the sets:

```
sage: BT = CombinatorialSpecies(min=1)
sage: Leaf =  SingletonSpecies()
sage: BT.define( Leaf + (BT*BT) )
```

Now we can construct the set of trees with five nodes, list them, count them…:

```
sage: BT5 = BT.isotypes([o]*5)                                        #␣
↪needs sage.symbolic
```

(continues on next page)

(continued from previous page)

```
sage: BT5.cardinality()                                                    #␣
↪needs sage.symbolic
14
sage: BT5.list()                                                           #␣
↪needs sage.symbolic
[o*(o*(o*(o*o))), o*(o*((o*o)*o)), o*((o*o)*(o*o)),
 o*((o*(o*o))*o), o*(((o*o)*o)*o), (o*o)*(o*(o*o)),
 (o*o)*((o*o)*o), (o*(o*o))*(o*o), ((o*o)*o)*(o*o),
 (o*(o*(o*o)))*o, (o*((o*o)*o))*o, ((o*o)*(o*o))*o,
 ((o*(o*o))*o)*o, (((o*o)*o)*o)*o]
```

The trees are constructed using a generic recursive structure; the display is therefore not wonderful. To do better, it would be necessary to provide Sage with a more specialized data structure with the desired display capabilities.

We recover the generating function for the Catalan numbers:

```
sage: g = BT.isotype_generating_series(); g
z + z^2 + 2*z^3 + 5*z^4 + 14*z^5 + 42*z^6 + 132*z^7 + O(z^8)
```

which is returned in the form of a lazy power series:

```
sage: g[100]
227508830794229349661819540395688853956041682601541047340
```

We finish with the Fibonacci words, which are binary words without two consecutive "1"s. They admit a natural recursive definition:

```
sage: Eps =  EmptySetSpecies()
sage: Z0  =  SingletonSpecies()
sage: Z1  =  Eps*SingletonSpecies()
sage: FW  = CombinatorialSpecies()
sage: FW.define(Eps + Z0*FW  +  Z1*Eps + Z1*Z0*FW)
```

The Fibonacci sequence is easily recognized here, hence the name:

```
sage: L = FW.isotype_generating_series()[:15]; L
[1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987]
```

```
sage: oeis(L)                                             # optional -- internet
0: A000045: Fibonacci numbers: F(n) = F(n-1) + F(n-2) with F(0) = 0 and F(1) = 1.
1: ...
2: ...
```

This is an immediate consequence of the recurrence relation. One can also generate immediately all the Fibonacci words of a given length, with the same limitations resulting from the generic display.

```
sage: FW3 = FW.isotypes([o]*3)                                             #␣
↪needs sage.symbolic
sage: FW3.list()                                                           #␣
↪needs sage.symbolic
[o*(o*(o*{})), o*(o*(({}*o)*{})), o*((({}*o)*o)*{}),
 (({}*o)*o)*(o*{}), (({}*o)*o)*(({}*o)*{})]
```

Graphs up to isomorphism

We saw in *Some other finite enumerated sets* that `Sage` could generate graphs and partial orders up to isomorphism. We will now describe the underlying algorithm, which is the same in both cases, and covers a substantially wider class of problems.

We begin by recalling some notions. A graph $G = (V, E)$ is a set V of vertices and a set E of edges connecting these vertices; an edge is described by a pair $\{u, v\}$ of distinct vertices of V. Such a graph is called labelled; its vertices are typically numbered by considering $V = \{1, 2, 3, 4, 5\}$.

In many problems, the labels on the vertices play no role. Typically a chemist wants to study all the possible molecules with a given composition, for example the alkanes with $n = 8$ atoms of carbon and $2n + 2 = 18$ atoms of hydrogen. He therefore wants to find all the graphs consisting of 8 vertices with 4 neighbours, and 18 vertices with a single neighbour. The different carbon atoms, however, are all considered to be identical, and the same for the hydrogen atoms. The problem of our chemist is not imaginary; this type of application is actually at the origin of an important part of the research in graph theory on isomorphism problems.

Working by hand on a small graph it is possible, as in the example of *Some other finite enumerated sets*, to make a drawing, erase the labels, and "forget" the geometrical information about the location of the vertices in the plane. However, to represent a graph in a computer program, it is necessary to introduce labels on the vertices so as to be able to describe how the edges connect them together. To compensate for the extra information which we have introduced, we then say that two labelled graphs g_1 and g_2 are *isomorphic* if there is a bijection from the vertices of g_1 to those of g_2, which maps bijectively the edges of g_1 to those of g_2; an *unlabelled graph* is then an equivalence class of labelled graphs.

In general, testing if two labelled graphs are isomorphic is expensive. However, the number of graphs, even unlabelled, grows very rapidly. Nonetheless, it is possible to list unlabelled graphs very efficiently considering their number. For example, the program `Nauty` can list the 12005168 simple graphs with 10 vertices in 20 seconds.

As in *Lexicographic generation of lists of integers*, the general principle of the algorithm is to organize the objects to be enumerated into a tree that one traverses.

For this, in each equivalence class of labelled graphs (that is to say, for each unlabelled graph) one fixes a convenient canonical representative. The following are the fundamental operations:

- Testing whether a labelled graph is canonical
- Calculating the canonical representative of a labelled graph

These unavoidable operations remain expensive; one therefore tries to minimize the number of calls to them.

The canonical representatives are chosen in such a way that, for each canonical labelled graph G, there is a canonical choice of an edge whose removal produces a canonical graph again, which is called the father of G. This property implies that it is possible to organize the set of canonical representatives as a tree: at the root, the graph with no edges; below it, its unique child, the graph with one edge; then the graphs with two edges, and so on. The set of children of a graph G can be constructed by *augmentation*, adding an edge in all the possible ways to G, and then selecting, from among those graphs, the ones that are still canonical[2]. Recursively, one obtains all the canonical graphs.

In what sense is this algorithm generic? Consider for example planar graphs (graphs which can be drawn in the plane without edges crossing): by removing an edge from a planar graph, one obtains another planar graph; so planar graphs form a subtree of the previous tree. To generate them, exactly the same algorithm can be used, selecting only the children which are planar:

```
sage: [len(list(graphs(n, property=lambda G: G.is_planar())))
....:  for n in range(7)]
[1, 1, 2, 4, 11, 33, 142]
```

[2] In practice, an efficient implementation would exploit the symmetries of G, i.e., its automorphism group, to reduce the number of children to explore, and to reduce the cost of each test of canonicity.

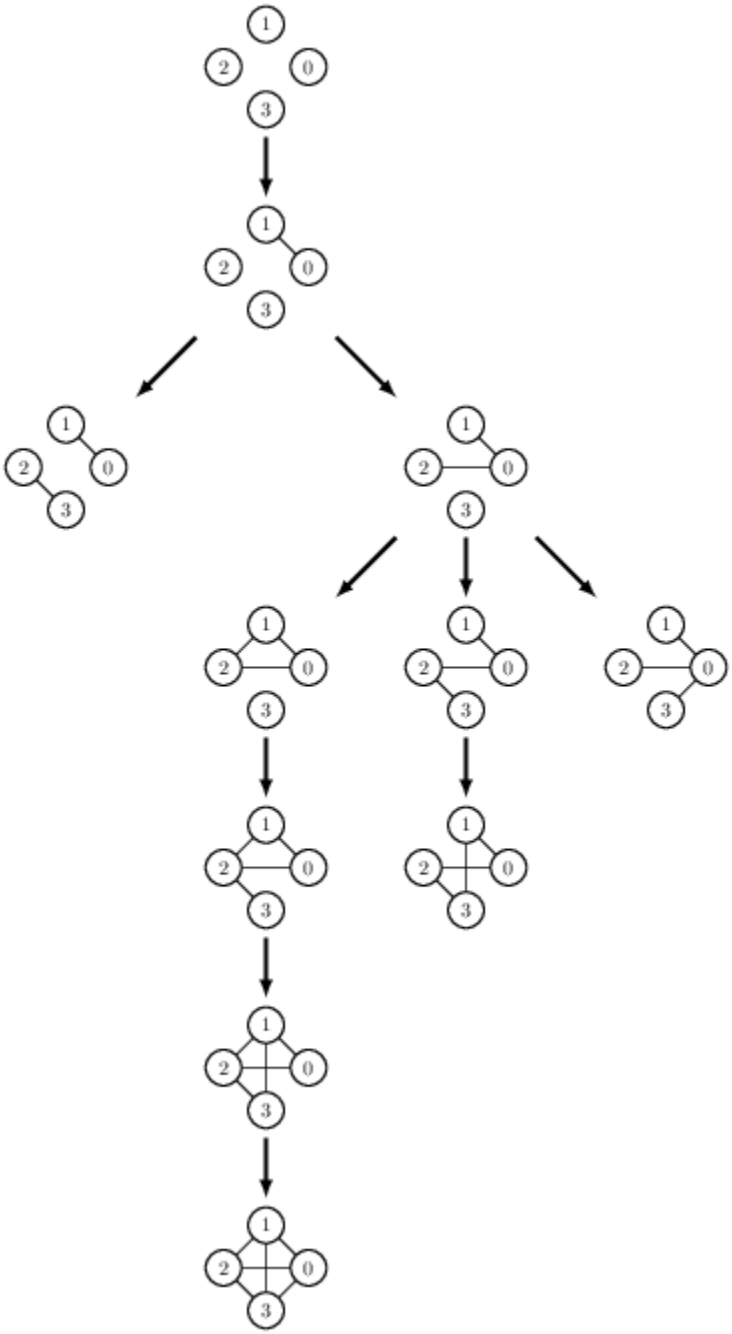

Fig. 4: Figure: The generation tree of simple graphs with 4 vertices.

In a similar fashion, one can generate any family of graphs closed under deletion of an edge, and in particular any family characterized by a forbidden subgraph. This includes for example forests (graphs without cycles), bipartite graphs (graphs without odd cycles), etc. This can be applied to generate:

- partial orders, via the bijection with Hasse diagrams which are oriented graphs without cycles and without edges implied by the transitivity of the order relation;
- lattices (not implemented in `Sage`), via the bijection with the meet semi-lattice obtained by deleting the maximal vertex; in this case an augmentation by vertices rather than by edges is used.

5.1.354 Vector Partitions

AUTHORS:

- Amritanshu Prasad (2013): Initial version
- Shriya M (2022): Added new parameters such as `distinct`, `parts` and `is_repeatable`

`sage.combinat.vector_partition.`**`IntegerVectorsIterator`**(*vect*, *min=None*)

Return an iterator over the list of integer vectors which are componentwise less than or equal to `vect`, and lexicographically greater than or equal to `min`.

INPUT:

- `vect` – A list of non-negative integers
- `min` – A list of non-negative integers dominated elementwise by `vect`

OUTPUT:

A list in lexicographic order of all integer vectors (as lists) which are dominated elementwise by `vect` and are greater than or equal to `min` in lexicographic order.

EXAMPLES:

```
sage: from sage.combinat.vector_partition import IntegerVectorsIterator
sage: list(IntegerVectorsIterator([1, 1]))
[[0, 0], [0, 1], [1, 0], [1, 1]]

sage: list(IntegerVectorsIterator([1, 1], min = [1, 0]))
[[1, 0], [1, 1]]
```

class `sage.combinat.vector_partition.`**`VectorPartition`**(*parent*, *vecpar*)

Bases: *CombinatorialElement*

A vector partition is a multiset of integer vectors.

`partition_at_vertex`(*i*)

Return the partition obtained by sorting the `i`-th elements of the vectors in the vector partition.

EXAMPLES:

```
sage: V = VectorPartition([[1, 2, 1], [2, 4, 1]])
sage: V.partition_at_vertex(1)
[4, 2]
```

sum()

Return the sum vector as a list.

EXAMPLES:

```
sage: V = VectorPartition([[3, 2, 1], [2, 2, 1]])
sage: V.sum()
[5, 4, 2]
```

class sage.combinat.vector_partition.**VectorPartitions**(*vec*, *min=None*, *parts=None*, *distinct=False*, *is_repeatable=None*)

Bases: UniqueRepresentation, Parent

Class of all vector partitions of `vec` with all parts greater than or equal to `min` in lexicographic order, with parts from `parts`.

A vector partition of `vec` is a list of vectors with non-negative integer entries whose sum is `vec`.

INPUT:

- `vec` – Integer vector
- `min` – Integer vector dominated elementwise by `vec`
- `parts` – Finite list of possible parts
- `distinct` – Boolean, set to `True` if only vector partitions with distinct parts are enumerated
- `is_repeatable` – Boolean function on `parts` which gives `True` in parts that can be repeated

EXAMPLES:

If `min` is not specified, then the class of all vector partitions of `vec` is created:

```
sage: VP = VectorPartitions([2, 2])
sage: for vecpar in VP:
....:     print(vecpar)
[[0, 1], [0, 1], [1, 0], [1, 0]]
[[0, 1], [0, 1], [2, 0]]
[[0, 1], [1, 0], [1, 1]]
[[0, 1], [2, 1]]
[[0, 2], [1, 0], [1, 0]]
[[0, 2], [2, 0]]
[[1, 0], [1, 2]]
[[1, 1], [1, 1]]
[[2, 2]]
```

If `distinct` is set to be True, then distinct part partitions are created:

```
sage: VP = VectorPartitions([2,2], distinct = True)
sage: list(VP)
[[[0, 1], [1, 0], [1, 1]],
 [[0, 1], [2, 1]],
 [[0, 2], [2, 0]],
 [[1, 0], [1, 2]],
 [[2, 2]]]
```

If `min` is specified, then the class consists of only those vector partitions whose parts are all greater than or equal to `min` in lexicographic order:

```
sage: VP = VectorPartitions([2, 2], min = [1, 0])
sage: for vecpar in VP:
....:     print(vecpar)
[[1, 0], [1, 2]]
[[1, 1], [1, 1]]
[[2, 2]]
sage: VP = VectorPartitions([2, 2], min = [1, 0], distinct = True)
sage: for vecpar in VP:
....:     print(vecpar)
[[1, 0], [1, 2]]
[[2, 2]]
```

If `parts` is specified, then the class consists only of those vector partitions whose parts are from `parts`:

```
sage: Vec_Par = VectorPartitions([2,2], parts=[[0,1],[1,0],[1,1]])
sage: list(Vec_Par)
[[[0, 1], [0, 1], [1, 0], [1, 0]], [[0, 1], [1, 0], [1, 1]], [[1, 1], [1, 1]]]
```

If `is_repeatable` is specified, then the parts which satisfy the boolean function `is_repeatable` are allowed to be repeated:

```
sage: Vector_Partitions = VectorPartitions([2,2], parts=[[0,1],[1,0],[1,1]], is_
↪repeatable=lambda vec: sum(vec)%2!=0)
sage: list(Vector_Partitions)
[[[0, 1], [0, 1], [1, 0], [1, 0]], [[0, 1], [1, 0], [1, 1]]]
```

Element

alias of *VectorPartition*

sage.combinat.vector_partition.**find_min**(*vect*)

Return a string of `0`'s with one `1` at the location where the list `vect` has its last entry which is not equal to `0`.

INPUT:

- `vec` – A list of integers

OUTPUT:

A list of the same length with `0`'s everywhere, except for a `1` at the last position where `vec` has an entry not equal to `0`.

EXAMPLES:

```
sage: from sage.combinat.vector_partition import find_min
sage: find_min([2, 1])
[0, 1]
sage: find_min([2, 1, 0])
[0, 1, 0]
```

5.1.355 Abstract word (finite or infinite)

This module gathers functions that works for both finite and infinite words.

AUTHORS:

- Sébastien Labbé
- Franco Saliola

EXAMPLES:

```
sage: a = 0.618
sage: g = words.CodingOfRotationWord(alpha=a, beta=1-a, x=a)
sage: f = words.FibonacciWord()
sage: p = f.longest_common_prefix(g, length='finite')
sage: p
word: 010010100100101001010010010100100101001010010...
sage: p.length()
231
```

class sage.combinat.words.abstract_word.**Word_class**

Bases: SageObject

apply_morphism(*morphism*)

Returns the word obtained by applying the morphism to self.

INPUT:

- morphism – Can be an instance of WordMorphism, or anything that can be used to construct one.

EXAMPLES:

```
sage: w = Word("ab")
sage: d = {'a':'ab', 'b':'ba'}
sage: w.apply_morphism(d)
word: abba
sage: w.apply_morphism(WordMorphism(d))
word: abba
```

```
sage: w = Word('ababa')
sage: d = dict(a='ab', b='ba')
sage: d
{'a': 'ab', 'b': 'ba'}
sage: w.apply_morphism(d)
word: abbaabbaab
```

For infinite words:

```
sage: t = words.ThueMorseWord([0,1]); t
word: 011010011001011010010110011010011001010110...
sage: t.apply_morphism({0:8,1:9})
word: 899898899889899898899889989988998898898998...
```

complete_return_words_iterator(*fact*)

Returns an iterator over all the complete return words of fact in self (without unicity).

A complete return words u of a factor v is a factor starting by the given factor v and ending just after the next occurrence of this factor v. See for instance [1].

INPUT:

- `fact` – a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.complete_return_words_iterator(fact)
sage: next(it)
word: 01101001100101101
sage: next(it)
word: 0110100101100101101
sage: next(it)
word: 011010011001011001101
sage: next(it)
word: 0110100101101
sage: next(it)
word: 01101001100101101
sage: next(it)
word: 0110100101100101101
```

REFERENCES:

- [1] J. Justin, L. Vuillon, Return words in Sturmian and episturmian words, Theor. Inform. Appl. 34 (2000) 343–356.

delta()

Returns the image of self under the delta morphism.

This is the word composed of the length of consecutive runs of the same letter in a given word.

OUTPUT:

Word over integers

EXAMPLES:

For finite words:

```
sage: W = Words('0123456789')
sage: W('22112122').delta()
word: 22112
sage: W('555008').delta()
word: 321
sage: W().delta()
word:
sage: Word('aabbabaa').delta()
word: 22112
```

For infinite words:

```
sage: t = words.ThueMorseWord()
sage: t.delta()
word: 12112221121121122211222112221121121122221...
```

factor_occurrences_iterator(*fact*)

Returns an iterator over all occurrences (including overlapping ones) of fact in self in their order of appearance.

INPUT:

- `fact` – a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.factor_occurrences_iterator(fact)
sage: next(it)
0
sage: next(it)
12
sage: next(it)
24
```

```
sage: u = Word('121')
sage: w = Word('1212132112l3')
sage: list(w.factor_occurrences_iterator(u))
[0, 2, 8]
```

finite_differences(*mod=None*)

Return the word obtained by the differences of consecutive letters of `self`.

INPUT:

- `self` – A word over the integers.
- **mod – (default: None) It can be one of the following:**
  - None or 0 : result is over the integers
  - integer : result is over the integers modulo `mod`.

EXAMPLES:

```
sage: w = Word([x^2 for x in range(10)])
sage: w.finite_differences()
word: 1,3,5,7,9,11,13,15,17
sage: w.finite_differences(mod=4)
word: 131313131
sage: w.finite_differences(mod=0)
word: 1,3,5,7,9,11,13,15,17
```

first_occurrence(*other*, *start=0*)

Return the position of the first occurrence of `other` in `self`.

If `other` is not a factor of `self`, it returns `None` or loops forever when `self` is an infinite word.

INPUT:

- `other` – a finite word
- `start` – integer (default:`0`), where the search starts

OUTPUT:

integer or `None`

EXAMPLES:

```
sage: w = Word('01234567890123456789')
sage: w.first_occurrence(Word('3456'))
3
sage: w.first_occurrence(Word('3456'), start=7)
13
```

When the factor is not present, `None` is returned:

```
sage: w.first_occurrence(Word('3456'), start=17) is None
True
sage: w.first_occurrence(Word('3333')) is None
True
```

Also works for searching a finite word in an infinite word:

```
sage: w = Word('0123456789')^oo
sage: w.first_occurrence(Word('3456'))
3
sage: w.first_occurrence(Word('3456'), start=1000)
1003
```

But it will loop for ever if the factor is not found:

```
sage: w.first_occurrence(Word('3333')) # not tested -- infinite loop
```

The empty word occurs in a word:

```
sage: Word('123').first_occurrence(Word(''), 0)
0
sage: Word('').first_occurrence(Word(''), 0)
0
```

is_empty()

Returns True if the length of self is zero, and False otherwise.

EXAMPLES:

```
sage: it = iter([])
sage: Word(it).is_empty()
True
sage: it = iter([1,2,3])
sage: Word(it).is_empty()
False
sage: from itertools import count
sage: Word(count()).is_empty()
False
```

is_finite()

Returns whether this word is known to be finite.

Warning: A word defined by an iterator such that its end has never been reached will returns False.

EXAMPLES:

```
sage: Word([]).is_finite()
True
sage: Word('a').is_finite()
True
sage: TM = words.ThueMorseWord()
sage: TM.is_finite()
False
```

```
sage: w = Word(iter('a'*100))
sage: w.is_finite()
False
```

iterated_right_palindromic_closure (*f=None*, *algorithm='recursive'*)

Returns the iterated (f-)palindromic closure of self.

INPUT:

- `f` – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).
- `algorithm` – string (default: `'recursive'`) specifying which algorithm to be used when computing the iterated palindromic closure. It must be one of the two following values:
  - `'definition'` – computed using the definition
  - `'recursive'` – computation based on an efficient formula that recursively computes the iterated right palindromic closure without having to recompute the longest f-palindromic suffix at each iteration [2].

OUTPUT:

word – the iterated (f-)palindromic closure of self

EXAMPLES:

```
sage: Word('123').iterated_right_palindromic_closure()
word: 1213121
```

```
sage: w = Word('abc')
sage: w.iterated_right_palindromic_closure()
word: abacaba
```

```
sage: w = Word('aaa')
sage: w.iterated_right_palindromic_closure()
word: aaa
```

```
sage: w = Word('abbab')
sage: w.iterated_right_palindromic_closure()
word: ababaababababaababa
```

A right f-palindromic closure:

```
sage: f = WordMorphism('a->b,b->a')
sage: w = Word('abbab')
sage: w.iterated_right_palindromic_closure(f=f)
word: abbaabbaababbaabbaabbaababbaabbaab
```

An infinite word:

```
sage: t = words.ThueMorseWord('ab')
sage: t.iterated_right_palindromic_closure()
word: abababababaababaababababaababaababababaabab...
```

There are two implementations computing the iterated right f-palindromic closure, the latter being much more efficient:

```
sage: w = Word('abaab')
sage: u = w.iterated_right_palindromic_closure(algorithm='definition')
sage: v = w.iterated_right_palindromic_closure(algorithm='recursive')
sage: u
word: abaabaababaabaaba
sage: u == v
True
sage: w = words.RandomWord(8)
sage: u = w.iterated_right_palindromic_closure(algorithm='definition')
sage: v = w.iterated_right_palindromic_closure(algorithm='recursive')
sage: u == v
True
```

- [2] J. Justin, Episturmian morphisms and a Galois theorem on continued fractions, RAIRO Theoret. Informatics Appl. 39 (2005) 207-215.

length()

Returns the length of self.

lex_greater(*other*)

Returns True if self is lexicographically greater than other.

EXAMPLES:

```
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_greater(u)
False
sage: v.lex_greater(w)
True
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_greater(b)
False
sage: b.lex_greater(a)
True
```

For infinite words:

```
sage: t = words.ThueMorseWord()
sage: t[:10].lex_greater(t)
False
sage: t.lex_greater(t[:10])
True
```

lex_less(*other*)

Returns True if self is lexicographically less than other.

EXAMPLES:

```
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_less(u)
True
sage: v.lex_less(w)
False
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_less(b)
True
sage: b.lex_less(a)
False
```

For infinite words:

```
sage: t = words.ThueMorseWord()
sage: t.lex_less(t[:10])
False
sage: t[:10].lex_less(t)
True
```

longest_common_prefix(*other*, *length='unknown'*)

Returns the longest common prefix of self and other.

INPUT:

- `other` – word
- `length` – string (default: `'unknown'`) the length type of the resulting word if known. It may be one of the following:
  - `'unknown'`
  - `'finite'`
  - `'infinite'`

EXAMPLES:

```
sage: f = lambda n : add(Integer(n).digits(2)) % 2
sage: t = Word(f)
sage: u = t[:10]
sage: t.longest_common_prefix(u)
word: 0110100110
```

The longest common prefix of two equal infinite words:

```
sage: t1 = Word(f)
sage: t2 = Word(f)
sage: t1.longest_common_prefix(t2)
word: 011010011001011010010110011010011001011...
```

Useful to study the approximation of an infinite word:

```
sage: a = 0.618
sage: g = words.CodingOfRotationWord(alpha=a, beta=1-a, x=a)
sage: f = words.FibonacciWord()
sage: p = f.longest_common_prefix(g, length='finite')
sage: p.length()
231
```

longest_periodic_prefix(*period=1*)

Returns the longest prefix of self having the given period.

INPUT:

- `period` – positive integer (default: 1)

OUTPUT:

word

EXAMPLES:

```
sage: Word([]).longest_periodic_prefix()
word:
sage: Word([1]).longest_periodic_prefix()
word: 1
sage: Word([1,2]).longest_periodic_prefix()
word: 1
sage: Word([1,1,2]).longest_periodic_prefix()
word: 11
sage: Word([1,2,1,2,1,3]).longest_periodic_prefix(2)
word: 12121
sage: type(_)
<class 'sage.combinat.words.word.FiniteWord_iter_with_caching'>
sage: Word(lambda n:0).longest_periodic_prefix()
word: 00000000000000000000000000000000000000000...
```

palindrome_prefixes_iterator(*max_length=None*)

Returns an iterator over the palindrome prefixes of self.

INPUT:

- `max_length` – non negative integer or None (optional, default: None) the maximum length of the prefixes

OUTPUT:

iterator

EXAMPLES:

```
sage: w = Word('abaaba')
sage: for pp in w.palindrome_prefixes_iterator(): pp
word:
word: a
word: aba
word: abaaba
sage: for pp in w.palindrome_prefixes_iterator(max_length=4): pp
word:
word: a
word: aba
```

You can iterate over the palindrome prefixes of an infinite word:

```
sage: f = words.FibonacciWord()
sage: for pp in f.palindrome_prefixes_iterator(max_length=20): pp
word:
word: 0
word: 010
word: 010010
word: 01001010010
word: 0100101001001010010
```

parent()

Returns the parent of self.

partial_sums(*start*, *mod=None*)

Returns the word defined by the partial sums of its prefixes.

INPUT:

- `self` – A word over the integers.
- `start` – integer, the first letter of the resulting word.
- **mod – (default: None) It can be one of the following:**
  - None or 0 : result is over the integers
  - integer : result is over the integers modulo `mod`.

EXAMPLES:

```
sage: w = Word(range(10))
sage: w.partial_sums(0)
word: 0,0,1,3,6,10,15,21,28,36,45
sage: w.partial_sums(1)
word: 1,1,2,4,7,11,16,22,29,37,46
```

```
sage: w = Word([1,2,3,1,2,3,2,2,2,2])
sage: w.partial_sums(0, mod=None)
word: 0,1,3,6,7,9,12,14,16,18,20
sage: w.partial_sums(0, mod=0)
word: 0,1,3,6,7,9,12,14,16,18,20
sage: w.partial_sums(0, mod=8)
word: 01367146024
sage: w.partial_sums(0, mod=4)
word: 01323102020
sage: w.partial_sums(0, mod=2)
word: 01101100000
sage: w.partial_sums(0, mod=1)
word: 00000000000
```

prefixes_iterator(*max_length=None*)

Returns an iterator over the prefixes of self.

INPUT:

- `max_length` – non negative integer or None (optional, default: None) the maximum length of the prefixes

OUTPUT:

iterator

EXAMPLES:

```
sage: w = Word('abaaba')
sage: for p in w.prefixes_iterator(): p
word:
word: a
word: ab
word: aba
word: abaa
word: abaab
word: abaaba
sage: for p in w.prefixes_iterator(max_length=3): p
word:
word: a
word: ab
word: aba
```

You can iterate over the prefixes of an infinite word:

```
sage: f = words.FibonacciWord()
sage: for p in f.prefixes_iterator(max_length=8): p
word:
word: 0
word: 01
word: 010
word: 0100
word: 01001
word: 010010
word: 0100101
word: 01001010
```

return_words_iterator(*fact*)

Returns an iterator over all the return words of fact in self (without unicity).

INPUT:

- `fact` – a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```
sage: w = Word('baccabccbacbca')
sage: b = Word('b')
sage: list(w.return_words_iterator(b))
[word: bacca, word: bcc, word: bac]
```

```
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.return_words_iterator(fact)
sage: next(it)
word: 011010011001
sage: next(it)
word: 011010010110
sage: next(it)
word: 0110100110010110
sage: next(it)
```

(continues on next page)

(continued from previous page)

```
word: 01101001
sage: next(it)
word: 011010011001
sage: next(it)
word: 011010010110
```

string_rep()

Returns the (truncated) raw sequence of letters as a string.

EXAMPLES:

```
sage: Word('abbabaab').string_rep()
'abbabaab'
sage: Word([0, 1, 0, 0, 1]).string_rep()
'01001'
sage: Word([0,1,10,101]).string_rep()
'0,1,10,101'
sage: WordOptions(letter_separator='-')
sage: Word([0,1,10,101]).string_rep()
'0-1-10-101'
sage: WordOptions(letter_separator=',')
```

sum_digits(*base=2*, *mod=None*)

Return the sequence of the sum modulo `mod` of the digits written in base `base` of `self`.

INPUT:

- `self` – word over natural numbers
- `base` – integer (default : 2), greater or equal to 2
- `mod` – modulo (default: `None`), can take the following values:
  - integer – the modulo
  - `None` – the value `base` is considered for the modulo.

EXAMPLES:

The Thue-Morse word:

```
sage: from itertools import count
sage: Word(count()).sum_digits()
word: 01101001100101101001011001101001100101 10...
```

Sum of digits modulo 2 of the prime numbers written in base 2:

```
sage: Word(primes(1000)).sum_digits()                                    #␣
↪needs sage.libs.pari
word: 10011101001110101110110010111011100110 11...
```

Sum of digits modulo 3 of the prime numbers written in base 3:

```
sage: Word(primes(1000)).sum_digits(base=3)                              #␣
↪needs sage.libs.pari
word: 21000020200022212221210222210221221110 22...
sage: Word(primes(1000)).sum_digits(base=3, mod=3)                       #␣
↪needs sage.libs.pari
word: 21000020200022212221210222210221221110 22...
```

Sum of digits modulo 2 of the prime numbers written in base 3:

```
sage: Word(primes(1000)).sum_digits(base=3, mod=2)                              #␣
↪needs sage.libs.pari
word: 01111111111111111111111111111111111111111...
```

Sum of digits modulo 7 of the prime numbers written in base 10:

```
sage: Word(primes(1000)).sum_digits(base=10, mod=7)                             #␣
↪needs sage.libs.pari
word: 23502413544350410061324322413535460063 04...
```

Negative entries:

```
sage: w = Word([-1,0,1,2,3,4,5])
sage: w.sum_digits()
Traceback (most recent call last):
...
NotImplementedError: nth digit of Thue-Morse word is not implemented for␣
↪negative value of n
```

to_integer_word()

Returns a word over the integers whose letters are those output by self._to_integer_iterator()

EXAMPLES:

```
sage: from itertools import count
sage: w = Word(count()); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,
↪27,28,29,30,31,32,33,34,35,36,37,38,39,...
sage: w.to_integer_word()
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,
↪27,28,29,30,31,32,33,34,35,36,37,38,39,...
sage: w = Word(iter("abbacabba"), length="finite"); w
word: abbacabba
sage: w.to_integer_word()
word: 011020110
sage: w = Word(iter("abbacabba"), length="unknown"); w
word: abbacabba
sage: w.to_integer_word()
word: 011020110
```

5.1.356 Combinatorics on words

Main modules and their methods:

- *Abstract word (finite or infinite)*
- *Finite word*
- *Infinite word*
- *Alphabet*
- *Set of words*
- *Word paths*
- *Word morphisms/substitutions*

- *Shuffle product of words*
- *Suffix Tries and Suffix Trees*

Main classes and functions meant to be used by the user:

Word(), *FiniteWords*, *InfiniteWords*, *Words()*, *Alphabet()*, *WordMorphism*, *WordPaths*.

A list of common words can be accessed through `words.<tab>` and are listed in the *words catalog*.

Internal representation of words:

- *Word classes*
- *Fast word datatype using an array of unsigned char*
- *Datatypes for finite words*
- *Datatypes for words defined by iterators and callables*

Options:

- *User-customizable options for words*

See *WordOptions()*.

5.1.357 Alphabet

AUTHORS:

- Franco Saliola (2008-12-17) : merged into sage
- Vincent Delecroix and Stepan Starosta (2012): remove classes for alphabet and use other Sage classes otherwise (TotallyOrderedFiniteSet, FiniteEnumeratedSet, …). More shortcut to standard alphabets.

EXAMPLES:

```
sage: build_alphabet("ab")
{'a', 'b'}
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="NN")
Non negative integers
sage: build_alphabet(name="lower")
{'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p', 'q',
↪'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'}
```

`sage.combinat.words.alphabet.`**`Alphabet`**(*data=None*, *names=None*, *name=None*)

Return an object representing an ordered alphabet.

INPUT:

- `data` – the letters of the alphabet; it can be:
  - a list/tuple/iterable of letters; the iterable may be infinite
  - an integer n to represent $\{1, \ldots, n\}$, or infinity to represent **N**
- `names` – (optional) a list for the letters (i.e. variable names) or a string for prefix for all letters; if given a list, it must have the same cardinality as the set represented by `data`

- `name` – (optional) if given, then return a named set and can be equal to : `'lower'`, `'upper'`, `'space'`, `'underscore'`, `'punctuation'`, `'printable'`, `'binary'`, `'octal'`, `'decimal'`, `'hexadecimal'`, `'radix64'`.

  You can use many of them at once, separated by spaces : `'lower punctuation'` represents the union of the two alphabets `'lower'` and `'punctuation'`.

  Alternatively, `name` can be set to `"positive integers"` (or `"PP"`) or `"natural numbers"` (or `"NN"`).

  `name` cannot be combined with `data`.

EXAMPLES:

If the argument is a Set, it just returns it:

```
sage: build_alphabet(ZZ) is ZZ
True
sage: F = FiniteEnumeratedSet('abc')
sage: build_alphabet(F) is F
True
```

If a list, tuple or string is provided, then it builds a proper Sage class (`TotallyOrderedFiniteSet`):

```
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: F = build_alphabet('abc'); F
{'a', 'b', 'c'}
sage: print(type(F).__name__)
TotallyOrderedFiniteSet_with_category
```

If an integer and a set is given, then it constructs a `TotallyOrderedFiniteSet`:

```
sage: build_alphabet(3, ['a','b','c'])
{'a', 'b', 'c'}
```

If an integer and a string is given, then it considers that string as a prefix:

```
sage: build_alphabet(3, 'x')
{'x0', 'x1', 'x2'}
```

If no data is provided, `name` may be a string which describe an alphabet. The available names decompose into two families. The first one are 'positive integers', 'PP', 'natural numbers' or 'NN' which refer to standard set of numbers:

```
sage: build_alphabet(name="positive integers")
Positive integers
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="natural numbers")
Non negative integers
sage: build_alphabet(name="NN")
Non negative integers
```

The other families for the option `name` are among 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64' which refer to standard set of characters. Theses names may be combined by separating them by a space:

```
sage: build_alphabet(name="lower")
{'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p',
```

(continues on next page)

(continued from previous page)

```
↪'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'}
sage: build_alphabet(name="hexadecimal")
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', 'a', 'b', 'c', 'd', 'e', 'f'}
sage: build_alphabet(name="decimal punctuation")
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', ' ', ',', '.', ';', ':', '!',
↪'?'}
```

In the case the alphabet is built from a list or a tuple, the order on the alphabet is given by the elements themselves:

```
sage: A = build_alphabet([0,2,1])
sage: A(0) < A(2)
True
sage: A(2) < A(1)
False
```

If a different order is needed, you may use `TotallyOrderedFiniteSet` and set the option `facade` to `False`. That way, the comparison fits the order of the input:

```
sage: A = TotallyOrderedFiniteSet([4,2,6,1], facade=False)
sage: A(4) < A(2)
True
sage: A(1) < A(6)
False
```

Be careful, the element of the set in the last example are no more integers and do not compare equal with integers:

```
sage: type(A.an_element())
<class 'sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet_with_
↪category.element_class'>
sage: A(1) == 1
False
sage: 1 == A(1)
False
```

We give an example of an infinite alphabet indexed by the positive integers and the prime numbers:

```
sage: build_alphabet(oo, 'x')
Lazy family (x(i))_{i in Non negative integers}
sage: build_alphabet(Primes(), 'y')
Lazy family (y(i))_{i in Set of all prime numbers: 2, 3, 5, 7, ...}
```

`sage.combinat.words.alphabet.`**`build_alphabet`**(*data=None*, *names=None*, *name=None*)

Return an object representing an ordered alphabet.

INPUT:

- `data` – the letters of the alphabet; it can be:
  - a list/tuple/iterable of letters; the iterable may be infinite
  - an integer n to represent $\{1, \ldots, n\}$, or infinity to represent **N**
- `names` – (optional) a list for the letters (i.e. variable names) or a string for prefix for all letters; if given a list, it must have the same cardinality as the set represented by `data`
- `name` – (optional) if given, then return a named set and can be equal to : `'lower'`, `'upper'`, `'space'`, `'underscore'`, `'punctuation'`, `'printable'`, `'binary'`, `'octal'`, `'decimal'`, `'hexadecimal'`, `'radix64'`.

You can use many of them at once, separated by spaces : `'lower punctuation'` represents the union of the two alphabets `'lower'` and `'punctuation'`.

Alternatively, `name` can be set to `"positive integers"` (or `"PP"`) or `"natural numbers"` (or `"NN"`).

`name` cannot be combined with `data`.

EXAMPLES:

If the argument is a Set, it just returns it:

```
sage: build_alphabet(ZZ) is ZZ
True
sage: F = FiniteEnumeratedSet('abc')
sage: build_alphabet(F) is F
True
```

If a list, tuple or string is provided, then it builds a proper Sage class (`TotallyOrderedFiniteSet`):

```
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: F = build_alphabet('abc'); F
{'a', 'b', 'c'}
sage: print(type(F).__name__)
TotallyOrderedFiniteSet_with_category
```

If an integer and a set is given, then it constructs a `TotallyOrderedFiniteSet`:

```
sage: build_alphabet(3, ['a','b','c'])
{'a', 'b', 'c'}
```

If an integer and a string is given, then it considers that string as a prefix:

```
sage: build_alphabet(3, 'x')
{'x0', 'x1', 'x2'}
```

If no data is provided, `name` may be a string which describe an alphabet. The available names decompose into two families. The first one are 'positive integers', 'PP', 'natural numbers' or 'NN' which refer to standard set of numbers:

```
sage: build_alphabet(name="positive integers")
Positive integers
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="natural numbers")
Non negative integers
sage: build_alphabet(name="NN")
Non negative integers
```

The other families for the option `name` are among 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64' which refer to standard set of characters. Theses names may be combined by separating them by a space:

```
sage: build_alphabet(name="lower")
{'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p',
↪'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'}
sage: build_alphabet(name="hexadecimal")
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', 'a', 'b', 'c', 'd', 'e', 'f'}
sage: build_alphabet(name="decimal punctuation")
```

(continues on next page)

(continued from previous page)

```
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', ' ', ',', '.', ';', ':', '!',
↪'?'}
```

In the case the alphabet is built from a list or a tuple, the order on the alphabet is given by the elements themselves:

```
sage: A = build_alphabet([0,2,1])
sage: A(0) < A(2)
True
sage: A(2) < A(1)
False
```

If a different order is needed, you may use `TotallyOrderedFiniteSet` and set the option `facade` to `False`. That way, the comparison fits the order of the input:

```
sage: A = TotallyOrderedFiniteSet([4,2,6,1], facade=False)
sage: A(4) < A(2)
True
sage: A(1) < A(6)
False
```

Be careful, the element of the set in the last example are no more integers and do not compare equal with integers:

```
sage: type(A.an_element())
<class 'sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet_with_
↪category.element_class'>
sage: A(1) == 1
False
sage: 1 == A(1)
False
```

We give an example of an infinite alphabet indexed by the positive integers and the prime numbers:

```
sage: build_alphabet(oo, 'x')
Lazy family (x(i))_{i in Non negative integers}
sage: build_alphabet(Primes(), 'y')
Lazy family (y(i))_{i in Set of all prime numbers: 2, 3, 5, 7, ...}
```

5.1.358 Finite word

AUTHORS:

- Arnaud Bergeron
- Amy Glen
- Sébastien Labbé
- Franco Saliola
- Julien Leroy (March 2010): reduced_rauzy_graph

EXAMPLES:

Creation of a finite word

Finite words from Python strings, lists and tuples:

```
sage: Word("abbabaab")
word: abbabaab
sage: Word([0, 1, 1, 0, 1, 0, 0, 1])
word: 01101001
sage: Word( ('a', 0, 5, 7, 'b', 9, 8) )
word: a057b98
```

Finite words from functions:

```
sage: f = lambda n : n%3
sage: Word(f, length=13)
word: 0120120120120
```

Finite words from iterators:

```
sage: from itertools import count
sage: Word(count(), length=10)
word: 0123456789
```

```
sage: Word( iter('abbccdef') )
word: abbccdef
```

Finite words from words via concatenation:

```
sage: u = Word("abcccabba")
sage: v = Word([0, 4, 8, 8, 3])
sage: u * v
word: abcccabba04883
sage: v * u
word: 04883abcccabba
sage: u + v
word: abcccabba04883
sage: u^3 * v^(8/5)
word: abcccabbaabcccabbaabcccabba04883048
```

Finite words from infinite words:

```
sage: vv = v^Infinity
sage: vv[10000:10015]
word: 048830488304883
```

Finite words in a specific combinatorial class:

```
sage: W = Words("ab")
sage: W
Finite and infinite words over {'a', 'b'}
sage: W("abbabaab")
word: abbabaab
sage: W(["a","b","b","a","b","a","a","b"])
word: abbabaab
sage: W( iter('ababab') )
word: ababab
```

Finite word as the image under a morphism:

```
sage: m = WordMorphism({0:[4,4,5,0],5:[0,5,5],4:[4,0,0,0]})
sage: m(0)
word: 4450
sage: m(0, order=2)
word: 400040000554450
sage: m(0, order=3)
word: 40004450445044504000445044504450445044500550...
```

Note: The following two finite words have the same string representation:

```
sage: w = Word('010120')
sage: z = Word([0, 1, 0, 1, 2, 0])
sage: w
word: 010120
sage: z
word: 010120
```

but are not equal:

```
sage: w == z
False
```

Indeed, w and z are defined on different alphabets:

```
sage: w[2]
'0'
sage: z[2]
0
```

Functions and algorithms

There are more than 100 functions defined on a finite word. Here are some of them:

```
sage: w = Word('abaabbba'); w
word: abaabbba
sage: w.is_palindrome()
False
sage: w.is_lyndon()
False
sage: w.number_of_factors()
28
sage: w.critical_exponent()
3
```

```
sage: print(w.lyndon_factorization())
(ab, aabbb, a)
sage: print(w.crochemore_factorization())
(a, b, a, ab, bb, a)
```

```
sage: st = w.suffix_tree()
sage: st
Implicit Suffix Tree of the word: abaabbba
```

(continues on next page)

(continued from previous page)

```
sage: st.show(word_labels=True)                                                 #␣
↪needs sage.plot
```

```
sage: T = words.FibonacciWord('ab')
sage: T.longest_common_prefix(Word('abaababababbbbbb'))
word: abaababa
```

As matrix and many other sage objects, words have a parent:

```
sage: u = Word('xyxxyxyyy')
sage: u.parent()
Finite words over Set of Python objects of class 'object'
```

```
sage: v = Word('xyxxyxyyy', alphabet='xy')
sage: v.parent()
Finite words over {'x', 'y'}
```

Factors and Rauzy Graphs

Enumeration of factors, the successive values returned by `next(it)` can appear in a different order depending on hardware. Therefore we mark the three first results of the test `random`. The important test is that the iteration stops properly on the fourth call:

```
sage: w = Word([4,5,6])^7
sage: it = w.factor_iterator(4)
sage: next(it) # random
word: 6456
sage: next(it) # random
word: 5645
sage: next(it) # random
word: 4564
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

The set of factors:

```
sage: sorted(w.factor_set(3))
[word: 456, word: 564, word: 645]
sage: sorted(w.factor_set(4))
[word: 4564, word: 5645, word: 6456]
sage: w.factor_set().cardinality()
61
```

Rauzy graphs:

```
sage: f = words.FibonacciWord()[:30]
sage: f.rauzy_graph(4)                                                          #␣
↪needs sage.graphs
Looped digraph on 5 vertices
sage: f.reduced_rauzy_graph(4)                                                  #␣
↪needs sage.graphs
Looped multi-digraph on 2 vertices
```

Left-special and bispecial factors:

```
sage: f.number_of_left_special_factors(7)
1
sage: f.bispecial_factors()
[word: , word: 0, word: 010, word: 010010, word: 01001010010]
```

class sage.combinat.words.finite_word.**CallableFromListOfWords**(*words*)

Bases: tuple

A class to create a callable from a list of words. The concatenation of a list of words is obtained by creating a word from this callable.

class sage.combinat.words.finite_word.**Factorization**(*iterable=()*, */*)

Bases: list

A list subclass having a nicer representation for factorization of words.

class sage.combinat.words.finite_word.**FiniteWord_class**

Bases: *Word_class*

BWT()

Return the Burrows-Wheeler Transform (BWT) of self.

The *Burrows-Wheeler transform* of a finite word w is obtained from w by first listing the conjugates of w in lexicographic order and then concatenating the final letters of the conjugates in this order. See [BW1994].

EXAMPLES:

```
sage: Word('abaccaaba').BWT()
word: cbaabaaca
sage: Word('abaab').BWT()
word: bbaaa
sage: Word('bbabbaca').BWT()
word: cbbbbaaa
sage: Word('aabaab').BWT()
word: bbaaaa
sage: Word().BWT()
word:
sage: Word('a').BWT()
word: a
```

LZ_decomposition()

Return the Crochemore factorization of self as an ordered list of factors.

The *Crochemore factorization* or the *Lempel-Ziv decomposition* of a finite word w is the unique factorization: $(x_1, x_2, \ldots, x_n)$ of w with each x_i satisfying either: C1. x_i is a letter that does not appear in $u = x_1 \ldots x_{i-1}$; C2. x_i is the longest prefix of $v = x_i \ldots x_n$ that also has an occurrence beginning within $u = x_1 \ldots x_{i-1}$. See [Cro1983].

EXAMPLES:

```
sage: x = Word('abababb')
sage: x.crochemore_factorization()
(a, b, abab, b)
sage: mul(x.crochemore_factorization()) == x
True
sage: y = Word('abaababacabba')
sage: y.crochemore_factorization()
```

(continues on next page)

(continued from previous page)

```
(a, b, a, aba, ba, c, ab, ba)
sage: mul(y.crochemore_factorization()) == y
True
sage: x = Word([0,1,0,1,0,1,1])
sage: x.crochemore_factorization()
(0, 1, 0101, 1)
sage: mul(x.crochemore_factorization()) == x
True
```

abelian_complexity(*n*)

Return the number of abelian vectors of factors of length `n` of `self`.

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.abelian_complexity(i) for i in range(20)]
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
```

```
sage: w = words.ThueMorseWord()[:100]
sage: [w.abelian_complexity(i) for i in range(20)]
[1, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2]
```

abelian_vector()

Return the abelian vector of `self` counting the occurrences of each letter.

The vector is defined w.r.t. the order of the alphabet of the parent. See also *evaluation_dict()*.

INPUT:

- `self` – word having a parent on a finite alphabet

OUTPUT:

a list

EXAMPLES:

```
sage: W = Words('ab')
sage: W('aaabbbbb').abelian_vector()
[3, 5]
sage: W('a').abelian_vector()
[1, 0]
sage: W().abelian_vector()
[0, 0]
```

The result depends on the alphabet of the parent:

```
sage: W = Words('abc')
sage: W('aabaa').abelian_vector()
[4, 1, 0]
```

abelian_vectors(*n*)

Return the abelian vectors of factors of length `n` of `self`.

The vectors are defined w.r.t. the order of the alphabet of the parent.

OUTPUT:

a set of tuples

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: w = W([0,1,1,0,1,2,0,2,0,2])
sage: w.abelian_vectors(3)
{(1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1)}
sage: w[:5].abelian_vectors(3)
{(1, 2, 0)}
sage: w[5:].abelian_vectors(3)
{(1, 0, 2), (2, 0, 1)}
```

```
sage: w = words.FibonacciWord()[:100]
sage: sorted(w.abelian_vectors(0))
[(0, 0)]
sage: sorted(w.abelian_vectors(1))
[(0, 1), (1, 0)]
sage: sorted(w.abelian_vectors(7))
[(4, 3), (5, 2)]
```

The word must be defined with a parent on a finite alphabet:

```
sage: from itertools import count
sage: w = Word(count(), alphabet=NN)
sage: w[:2].abelian_vectors(2)
Traceback (most recent call last):
...
TypeError: The alphabet of the parent is infinite; define the
word with a parent on a finite alphabet
```

apply_permutation_to_letters(*permutation*)

Return the word obtained by applying the permutation `permutation` of the alphabet of `self` to each letter of `self`.

EXAMPLES:

```
sage: w = Words('abcd')('abcd')
sage: p = [2,1,4,3]
sage: w.apply_permutation_to_letters(p)
word: badc
sage: u = Words('dabc')('abcd')
sage: u.apply_permutation_to_letters(p)
word: dcba
sage: w.apply_permutation_to_letters(Permutation(p))
word: badc
sage: w.apply_permutation_to_letters(PermutationGroupElement(p))            #␣
↪needs sage.groups
word: badc
```

apply_permutation_to_positions(*permutation*)

Return the word obtained by permuting the positions of the letters in `self` according to the permutation `permutation`.

EXAMPLES:

```
sage: w = Words('abcd')('abcd')
sage: w.apply_permutation_to_positions([2,1,4,3])
word: badc
```

(continues on next page)

(continued from previous page)

```
sage: u = Words('dabc')('abcd')
sage: u.apply_permutation_to_positions([2,1,4,3])
word: badc
sage: w.apply_permutation_to_positions(Permutation([2,1,4,3]))
word: badc
sage: w.apply_permutation_to_positions(PermutationGroupElement([2,1,4,3]))  #␣
↪needs sage.groups
word: badc
sage: Word([1,2,3,4]).apply_permutation_to_positions([3,4,2,1])
word: 3421
```

balance()

Return the balance of `self`.

The balance of a word is the smallest number q such that `self` is q-balanced [FV2002].

A finite or infinite word w is said to be *q-balanced* if for any two factors u, v of w of the same length, the difference between the number of x's in each of u and v is at most q for all letters x in the alphabet of w. A 1-balanced word is simply said to be balanced. See Chapter 2 of [Lot2002].

OUTPUT:

integer

EXAMPLES:

```
sage: Word('1111111').balance()
0
sage: Word('001010101011').balance()
2
sage: Word('0101010101').balance()
1
```

```
sage: w = Word('11112222')
sage: w.is_balanced(2)
False
sage: w.is_balanced(3)
False
sage: w.is_balanced(4)
True
sage: w.is_balanced(5)
True
sage: w.balance()
4
```

bispecial_factors(*n=None*)

Return the bispecial factors (of length `n`).

A factor u of a word w is *bispecial* if it is right special and left special.

INPUT:

- `n` – integer (default: `None`). If `None`, it returns all bispecial factors.

OUTPUT:

a list of words

EXAMPLES:

```
sage: w = words.FibonacciWord()[:30]
sage: w.bispecial_factors()
[word: , word: 0, word: 010, word: 010010, word: 01001010010]
```

```
sage: w = words.ThueMorseWord()[:30]
sage: for i in range(10):
....:     print("{} {}".format(i, sorted(w.bispecial_factors(i))))
0 [word: ]
1 [word: 0, word: 1]
2 [word: 01, word: 10]
3 [word: 010, word: 101]
4 [word: 0110, word: 1001]
5 []
6 [word: 011001, word: 100110]
7 []
8 [word: 10010110]
9 []
```

bispecial_factors_iterator(*n=None*)

Return an iterator over the bispecial factors (of length `n`).

A factor u of a word w is *bispecial* if it is right special and left special.

INPUT:

- `n` – integer (default: `None`). If `None`, it returns an iterator over all bispecial factors.

EXAMPLES:

```
sage: w = words.ThueMorseWord()[:30]
sage: for i in range(10):
....:     for u in sorted(w.bispecial_factors_iterator(i)):
....:         print("{} {}".format(i,u))
0
1 0
1 1
2 01
2 10
3 010
3 101
4 0110
4 1001
6 011001
6 100110
8 10010110
```

```
sage: key = lambda u : (len(u), u)
sage: for u in sorted(w.bispecial_factors_iterator(), key=key): u
word:
word: 0
word: 1
word: 01
word: 10
word: 010
word: 101
word: 0110
word: 1001
word: 011001
```

(continues on next page)

(continued from previous page)

```
word: 100110
word: 10010110
```

border()

Return the longest word that is both a proper prefix and a proper suffix of `self`.

EXAMPLES:

```
sage: Word('121212').border()
word: 1212
sage: Word('12321').border()
word: 1
sage: Word().border() is None
True
```

charge(*check=True*)

Return the charge of `self`. This is defined as follows.

If w is a permutation of length n, (in other words, the evaluation of w is $(1, 1, \ldots, 1)$), the statistic charge(w) is given by $\sum_{i=1}^{n} c_i(w)$ where $c_1(w) = 0$ and $c_i(w)$ is defined recursively by setting p_i equal to 1 if i appears to the right of $i-1$ in w and 0 otherwise. Then we set $c_i(w) = c_{i-1}(w) + p_i$.

EXAMPLES:

```
sage: Word([1, 2, 3]).charge()
3
sage: Word([3, 5, 1, 4, 2]).charge() == 0 + 1 + 1 + 2 + 2
True
```

If w is not a permutation, but the evaluation of w is a partition, the charge of w is defined to be the sum of its charge subwords (each of which will be a permutation). The first charge subword is found by starting at the end of w and moving left until the first 1 is found. This is marked, and we continue to move to the left until the first 2 is found, wrapping around from the beginning of the word back to the end, if necessary. We mark this 2, and continue on until we have marked the largest letter in w. The marked letters, with relative order preserved, form the first charge subword of w. This subword is removed, and the next charge subword is found in the same manner from the remaining letters. In the following example, $w1, w2, w3$ are the charge subwords of w.

EXAMPLES:

```
sage: w = Word([5,2,3,4,4,1,1,1,2,2,3])
sage: w1 = Word([5, 2, 4, 1, 3])
sage: w2 = Word([3, 4, 1, 2])
sage: w3 = Word([1, 2])
sage: w.charge() == w1.charge() + w2.charge() + w3.charge()
True
```

Finally, if w does not have partition content, we apply the Lascoux-Schützenberger standardization operators s_i in such a manner as to obtain a word with partition content. (The word we obtain is independent of the choice of operators.) The charge is then defined to be the charge of this word:

```
sage: Word([3,3,2,1,1]).charge()
0
sage: Word([1,2,3,1,2]).charge()
2
```

Note that this differs from the definition of charge given in Macdonald's book. The difference amounts to a choice of reading a word from left-to-right or right-to-left. The choice in Sage was made to agree with the definition of a reading word of a tableau in Sage, and seems to be the more common convention in the literature.

See [Mac1995], [LLM2003], and [LLT].

cocharge()

Return the cocharge of `self`. For a word w, this can be defined as $n_{ev} - ch(w)$, where $ch(w)$ is the charge of w and ev is the evaluation of w, and n_{ev} is $\sum_{i<j} min(ev_i, ev_j)$.

EXAMPLES:

```
sage: Word([1,2,3]).cocharge()
0
sage: Word([3,2,1]).cocharge()
3
sage: Word([1,1,2]).cocharge()
0
sage: Word([2,1,2]).cocharge()
1
```

coerce(*other*)

Try to return a pair of words with a common parent; raise an exception if this is not possible.

This function begins by checking if both words have the same parent. If this is the case, then no work is done and both words are returned as-is.

Otherwise it will attempt to convert `other` to the domain of `self`. If that fails, it will attempt to convert `self` to the domain of `other`. If both attempts fail, it raises a `TypeError` to signal failure.

EXAMPLES:

```
sage: W1 = Words('abc'); W2 = Words('ab')
sage: w1 = W1('abc'); w2 = W2('abba'); w3 = W1('baab')
sage: w1.parent() is w2.parent()
False
sage: a, b = w1.coerce(w2)
sage: a.parent() is b.parent()
True
sage: w1.parent() is w2.parent()
False
```

colored_vector(*x=0*, *y=0*, *width='default'*, *height=1*, *cmap='hsv'*, *thickness=1*, *label=None*)

Return a vector (Graphics object) illustrating `self`. Each letter is represented by a coloured rectangle.

If the parent of `self` is a class of words over a finite alphabet, then each letter in the alphabet is assigned a unique colour, and this colour will be the same every time this method is called. This is especially useful when plotting and comparing words defined on the same alphabet.

If the alphabet is infinite, then the letters appearing in the word are used as the alphabet.

INPUT:

- `x` – (default: `0`) bottom left x-coordinate of the vector
- `y` – (default: `0`) bottom left y-coordinate of the vector
- `width` – (default: `'default'`) width of the vector. By default, the width is the length of `self`.
- `height` – (default: `1`) height of the vector

- `thickness` – (default: `1`) thickness of the contour
- `cmap` – (default: `'hsv'`) color map; for available color map names type: `import matplotlib.cm; list(matplotlib.cm.datad)`
- `label` – string (default: `None`) a label to add on the colored vector

OUTPUT:

Graphics

EXAMPLES:

```
sage: # needs sage.plot
sage: Word(range(20)).colored_vector()
Graphics object consisting of 21 graphics primitives
sage: Word(range(100)).colored_vector(0,0,10,1)
Graphics object consisting of 101 graphics primitives
sage: Words(range(100))(range(10)).colored_vector()
Graphics object consisting of 11 graphics primitives
sage: w = Word('abbabaab')
sage: w.colored_vector()
Graphics object consisting of 9 graphics primitives
sage: w.colored_vector(cmap='autumn')
Graphics object consisting of 9 graphics primitives
sage: Word(range(20)).colored_vector(label='Rainbow')
Graphics object consisting of 23 graphics primitives
```

When two words are defined under the same parent, same letters are mapped to same colors:

```
sage: W = Words(range(20))
sage: w = W(range(20))
sage: y = W(range(10,20))
sage: y.colored_vector(y=1, x=10) + w.colored_vector()                    #␣
↪needs sage.plot
Graphics object consisting of 32 graphics primitives
```

commutes_with(*other*)

Return `True` if `self` commutes with `other`, and `False` otherwise.

EXAMPLES:

```
sage: Word('12').commutes_with(Word('12'))
True
sage: Word('12').commutes_with(Word('11'))
False
sage: Word().commutes_with(Word('21'))
True
```

complete_return_words(*fact*)

Return the set of complete return words of `fact` in `self`.

This is the set of all factors starting by the given factor and ending just after the next occurrence of this factor. See for instance [JV2000].

INPUT:

- `fact` – a non-empty finite word

OUTPUT:

a Python set of finite words

EXAMPLES:

```
sage: s = Word('21331233213231').complete_return_words(Word('2'))
sage: sorted(s)
[word: 2132, word: 213312, word: 2332]
sage: Word('').complete_return_words(Word('213'))
set()
sage: Word('121212').complete_return_words(Word('1212'))
{word: 121212}
```

concatenate(*other*)

Return the concatenation of `self` and `other`.

INPUT:

- `other` – a word over the same alphabet as `self`

EXAMPLES:

Concatenation may be made using + or * operations:

```
sage: w = Word('abadafd')
sage: y = Word([5,3,5,8,7])
sage: w * y
word: abadafd53587
sage: w + y
word: abadafd53587
sage: w.concatenate(y)
word: abadafd53587
```

Both words must be defined over the same alphabet:

```
sage: z = Word('12223', alphabet = '123')
sage: z + y
Traceback (most recent call last):
...
ValueError: 5 not in alphabet
```

Eventually, it should work:

```
sage: z = Word('12223', alphabet = '123')
sage: z + y                    #todo: not implemented
word: 1222353587
```

conjugate(*pos*)

Return the conjugate at `pos` of `self`.

`pos` can be any integer, the distance used is the modulo by the length of `self`.

EXAMPLES:

```
sage: Word('12112').conjugate(1)
word: 21121
sage: Word().conjugate(2)
word:
sage: Word('12112').conjugate(8)
word: 12121
sage: Word('12112').conjugate(-1)
word: 21211
```

conjugate_position(*other*)

Return the position where `self` is conjugate with `other`. Return `None` if there is no such position.

EXAMPLES:

```
sage: Word('12113').conjugate_position(Word('31211'))
1
sage: Word('12131').conjugate_position(Word('12113')) is None
True
sage: Word().conjugate_position(Word('123')) is None
True
```

conjugates()

Return the list of unique conjugates of `self`.

EXAMPLES:

```
sage: Word(range(6)).conjugates()
[word: 012345,
 word: 123450,
 word: 234501,
 word: 345012,
 word: 450123,
 word: 501234]
sage: Word('cbbca').conjugates()
[word: cbbca, word: bbcac, word: bcacb, word: cacbb, word: acbbc]
```

The result contains each conjugate only once:

```
sage: Word('abcabc').conjugates()
[word: abcabc, word: bcabca, word: cabcab]
```

conjugates_iterator()

Return an iterator over the conjugates of `self`.

EXAMPLES:

```
sage: it = Word(range(4)).conjugates_iterator()
sage: for w in it: w
word: 0123
word: 1230
word: 2301
word: 3012
```

content(*n=None*)

Return content of `self`.

INPUT:

- `n` – (optional) an integer specifying the maximal letter in the alphabet

OUTPUT:

- a list where the i-th entry indicates the multiplicity of the i-th letter in the alphabet in `self`

EXAMPLES:

```
sage: w = Word([1,2,4,3,2,2,2])
sage: w.content()
```

(continues on next page)

(continued from previous page)

```
[1, 4, 1, 1]
sage: w = Word([3,1])
sage: w.content()
[1, 1]
sage: w.content(n=3)
[1, 0, 1]
sage: w = Word([2,4],alphabet=[1,2,3,4])
sage: w.content(n=3)
[0, 1, 0]
sage: w.content()
[0, 1, 0, 1]
```

count(*letter*)

Return the number of occurrences of `letter` in `self`.

INPUT:

- `letter` – a letter

OUTPUT:

- integer

EXAMPLES:

```
sage: w = Word('abbabaab')
sage: w.number_of_letter_occurrences('a')
4
sage: w.number_of_letter_occurrences('ab')
0
```

This methods is equivalent to `list(w).count(letter)` and `tuple(w).count(letter)`, thus `count` is an alias for the method `number_of_letter_occurrences`:

```
sage: list(w).count('a')
4
sage: w.count('a')
4
```

But notice that if `s` and `w` are strings, `Word(s).count(w)` counts the number occurrences of `w` as a letter in `Word(s)` which is not the same as `s.count(w)` which counts the number of occurrences of the string `w` inside `s`:

```
sage: s = 'abbabaab'
sage: s.count('ab')
3
sage: Word(s).count('ab')
0
```

See also:

sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()

critical_exponent()

Return the critical exponent of `self`.

The *critical exponent* of a word is the supremum of the order of all its (finite) factors. See [Dej1972].

Note: The implementation here uses the suffix tree to enumerate all the factors. It should be improved (especially when the critical exponent is larger than 2).

EXAMPLES:

```
sage: Word('aaba').critical_exponent()
2
sage: Word('aabaa').critical_exponent()
2
sage: Word('aabaaba').critical_exponent()
7/3
sage: Word('ab').critical_exponent()
1
sage: Word('aba').critical_exponent()
3/2
sage: words.ThueMorseWord()[:20].critical_exponent()
2
```

For the Fibonacci word, the critical exponent is known to be $(5+\sqrt(5))/2$. With a prefix of length 500, we obtain a lower bound:

```
sage: words.FibonacciWord()[:500].critical_exponent()
320/89
```

It is an error to compute the critical exponent of the empty word:

```
sage: Word('').critical_exponent()
Traceback (most recent call last):
...
ValueError: no critical exponent for empty word
```

crochemore_factorization()

Return the Crochemore factorization of `self` as an ordered list of factors.

The *Crochemore factorization* or the *Lempel-Ziv decomposition* of a finite word w is the unique factorization: $(x_1, x_2, \ldots, x_n)$ of w with each x_i satisfying either: C1. x_i is a letter that does not appear in $u = x_1 \ldots x_{i-1}$; C2. x_i is the longest prefix of $v = x_i \ldots x_n$ that also has an occurrence beginning within $u = x_1 \ldots x_{i-1}$. See [Cro1983].

EXAMPLES:

```
sage: x = Word('abababb')
sage: x.crochemore_factorization()
(a, b, abab, b)
sage: mul(x.crochemore_factorization()) == x
True
sage: y = Word('abaababacabba')
sage: y.crochemore_factorization()
(a, b, a, aba, ba, c, ab, ba)
sage: mul(y.crochemore_factorization()) == y
True
sage: x = Word([0,1,0,1,0,1,1])
sage: x.crochemore_factorization()
(0, 1, 0101, 1)
sage: mul(x.crochemore_factorization()) == x
True
```

defect (*f=None*)

Return the defect of `self`.

The *defect* of a finite word w is given by the difference between the maximum number of possible palindromic factors in a word of length $|w|$ and the actual number of palindromic factors contained in w. It is well known that the maximum number of palindromic factors in w is $|w| + 1$ (see [DJP2001]).

An optional involution on letters `f` can be given. In that case, the *f-palindromic defect* (or *pseudopalindromic defect*, or *theta-palindromic defect*) of w is returned. It is a generalization of defect to f-palindromes. More precisely, the defect is $D(w) = |w| + 1 - g_f(w) - |PAL_f(w)|$, where $PAL_f(w)$ denotes the set of f-palindromic factors of w (including the empty word) and $g_f(w)$ is the number of pairs $\{a, f(a)\}$ such that a is a letter, a is not equal to $f(a)$, and a or $f(a)$ occurs in w. In the case of usual palindromes (i.e., for `f` not given or equal to the identity), $g_f(w) = 0$ for all w. See [BHNR2004] for usual palindromes and [Star2011] for f-palindromes.

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`). The default value corresponds to usual palindromes, i.e., `f` equal to the identity.

OUTPUT:

an integer – If `f` is `None`, the palindromic defect of `self`; otherwise, the `f`-palindromic defect of `self`.

EXAMPLES:

```
sage: Word('ara').defect()
0
sage: Word('abcacba').defect()
1
```

It is known that Sturmian words (see [DJP2001]) have zero defect:

```
sage: words.FibonacciWord()[:100].defect()
0

sage: sa = WordMorphism('a->ab,b->b')
sage: sb = WordMorphism('a->a,b->ba')
sage: w = (sa*sb*sb*sa*sa*sa*sb).fixed_point('a')
sage: w[:30].defect()                                                       #␣
↪needs sage.modules
0
sage: w[110:140].defect()                                                   #␣
↪needs sage.modules
0
```

It is even conjectured that the defect of an aperiodic word which is a fixed point of a primitive morphism is either 0 or infinite (see [BBGL2008]):

```
sage: w = words.ThueMorseWord()
sage: w[:50].defect()                                                       #␣
↪needs sage.modules
12
sage: w[:100].defect()                                                      #␣
↪needs sage.modules
16
sage: w[:300].defect()                                                      #␣
↪needs sage.modules
52
```

For generalized defect with an involution different from the identity, there is always a letter which is not a palindrome! This is the reason for the modification of the definition:

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('a').defect(f)
0
sage: Word('ab').defect(f)
0
sage: Word('aa').defect(f)
1
sage: Word('abbabaabbaababba').defect(f)
3
```

```
sage: f = WordMorphism('a->b,b->a,c->c')
sage: Word('cabc').defect(f)
0
sage: Word('abcaab').defect(f)
2
```

Other examples:

```
sage: Word('000000000000').defect()
0
sage: Word('011010011001').defect()
2
sage: Word('0101001010001').defect()
0
sage: Word().defect()
0
sage: Word('abbabaabbaababba').defect()
2
```

deg_inv_lex_less(*other*, *weights=None*)

Return `True` if the word `self` is degree inverse lexicographically less than `other`.

EXAMPLES:

```
sage: Word([1,2,4]).deg_inv_lex_less(Word([1,3,2]))
False
sage: Word([3,2,1]).deg_inv_lex_less(Word([1,2,3]))
True
```

deg_lex_less(*other*, *weights=None*)

Return `True` if `self` is degree lexicographically less than `other`, and `False` otherwise. The weight of each letter in the ordered alphabet is given by `weights`, which defaults to `[1, 2, 3, ...]`.

EXAMPLES:

```
sage: Word([1,2,3]).deg_lex_less(Word([1,3,2]))
True
sage: Word([3,2,1]).deg_lex_less(Word([1,2,3]))
False
sage: W = Words(range(5))
sage: W([1,2,4]).deg_lex_less(W([1,3,2]))
False
sage: Word("abba").deg_lex_less(Word("abbb"), dict(a=1,b=2))
True
```

(continues on next page)

(continued from previous page)

```
sage: Word("abba").deg_lex_less(Word("baba"), dict(a=1,b=2))
True
sage: Word("abba").deg_lex_less(Word("aaba"), dict(a=1,b=2))
False
sage: Word("abba").deg_lex_less(Word("aaba"), dict(a=1,b=0))
True
```

deg_rev_lex_less(*other*, *weights=None*)

Return `True` if `self` is degree reverse lexicographically less than `other`.

EXAMPLES:

```
sage: Word([3,2,1]).deg_rev_lex_less(Word([1,2,3]))
False
sage: Word([1,2,4]).deg_rev_lex_less(Word([1,3,2]))
False
sage: Word([1,2,3]).deg_rev_lex_less(Word([1,2,4]))
True
```

degree(*weights=None*)

Return the weighted degree of `self`, where the weighted degree of each letter in the ordered alphabet is given by `weights`, which defaults to `[1, 2, 3, ...]`.

INPUT:

- `weights` – a list or a tuple, or a dictionary keyed by the letters occurring in `self`.

EXAMPLES:

```
sage: Word([1,2,3]).degree()
6
sage: Word([3,2,1]).degree()
6
sage: Words("ab")("abba").degree()
6
sage: Words("ab")("abba").degree([0,2])
4
sage: Words("ab")("abba").degree([-1,-1])
-4
sage: Words("ab")("aabba").degree([1,1])
5
sage: Words([1,2,4])([1,2,4]).degree()
6
sage: Word([1,2,4]).degree()
7
sage: Word("aabba").degree({'a':1,'b':2})
7
sage: Word([0,1,0]).degree({0:17,1:0})
34
```

delta()

Return the image of `self` under the delta morphism.

The delta morphism, also known as the run-length encoding, is the word composed of the length of consecutive runs of the same letter in a given word.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('22112122').delta()
word: 22112
sage: W('555008').delta()
word: 321
sage: W().delta()
word:
sage: Word('aabbabaa').delta()
word: 22112
```

delta_derivate(*W=None*)

Return the derivative under delta for `self`.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate()
word: 22
sage: W('1').delta_derivate(Words([1]))
word: 1
sage: W('2112').delta_derivate()
word: 2
sage: W('2211').delta_derivate()
word: 22
sage: W('112').delta_derivate()
word: 2
sage: W('11222').delta_derivate(Words([1, 2, 3]))
word: 3
```

delta_derivate_left(*W=None*)

Return the derivative under delta for `self`.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate_left()
word: 22
sage: W('1').delta_derivate_left(Words([1]))
word: 1
sage: W('2112').delta_derivate_left()
word: 21
sage: W('2211').delta_derivate_left()
word: 22
sage: W('112').delta_derivate_left()
word: 21
sage: W('11222').delta_derivate_left(Words([1, 2, 3]))
word: 3
```

delta_derivate_right(*W=None*)

Return the right derivative under delta for `self`.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate_right()
word: 122
sage: W('1').delta_derivate_right(Words([1]))
```

(continues on next page)

(continued from previous page)

```
word: 1
sage: W('2112').delta_derivate_right()
word: 12
sage: W('2211').delta_derivate_right()
word: 22
sage: W('112').delta_derivate_right()
word: 2
sage: W('11222').delta_derivate_right(Words([1, 2, 3]))
word: 23
```

delta_inv(*W=None*, *s=None*)

Lift `self` via the delta operator to obtain a word containing the letters in alphabet (default is `[0, 1]`). The letters used in the construction start with `s` (default is `alphabet[0]`) and cycle through alphabet.

INPUT:

- `alphabet` – an iterable
- `s` – an object in the iterable

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([2, 2, 1, 1]).delta_inv()
word: 112212
sage: W([1, 1, 1, 1]).delta_inv(Words('123'))
word: 1231
sage: W([2, 2, 1, 1, 2]).delta_inv(s=2)
word: 22112122
```

evaluation()

Return the abelian vector of `self` counting the occurrences of each letter.

The vector is defined w.r.t. the order of the alphabet of the parent. See also *evaluation_dict()*.

INPUT:

- `self` – word having a parent on a finite alphabet

OUTPUT:

a list

EXAMPLES:

```
sage: W = Words('ab')
sage: W('aaabbbbb').abelian_vector()
[3, 5]
sage: W('a').abelian_vector()
[1, 0]
sage: W().abelian_vector()
[0, 0]
```

The result depends on the alphabet of the parent:

```
sage: W = Words('abc')
sage: W('aabaa').abelian_vector()
[4, 1, 0]
```

evaluation_dict()

Return a dictionary keyed by the letters occurring in `self` with values the number of occurrences of the letter.

EXAMPLES:

```
sage: Word([2,1,4,2,3,4,2]).evaluation_dict()
{1: 1, 2: 3, 3: 1, 4: 2}
sage: Word('badbcdb').evaluation_dict()
{'a': 1, 'b': 3, 'c': 1, 'd': 2}
sage: Word().evaluation_dict()
{}
```

```
sage: f = Word('1213121').evaluation_dict() # keys appear in random order
{'1': 4, '2': 2, '3': 1}
```

evaluation_partition()

Return the evaluation of the word w as a partition.

EXAMPLES:

```
sage: Word("acdabda").evaluation_partition()
[3, 2, 1, 1]
sage: Word([2,1,4,2,3,4,2]).evaluation_partition()
[3, 2, 1, 1]
```

evaluation_sparse()

Return a list representing the evaluation of `self`. The entries of the list are two-element lists `[a, n]`, where `a` is a letter occurring in `self` and `n` is the number of occurrences of `a` in `self`.

EXAMPLES:

```
sage: sorted(Word([4,4,2,5,2,1,4,1]).evaluation_sparse())
[(1, 2), (2, 2), (4, 3), (5, 1)]
sage: sorted(Word("abcaccab").evaluation_sparse())
[('a', 3), ('b', 2), ('c', 3)]
```

exponent()

Return the exponent of `self`.

OUTPUT:

integer – the exponent

EXAMPLES:

```
sage: Word('1231').exponent()
1
sage: Word('121212').exponent()
3
sage: Word().exponent()
0
```

factor_complexity(*n*)

Return the number of distinct factors of length `n` of `self`.

INPUT:

- `n` – the length of the factors.

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.factor_complexity(i) for i in range(20)]
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]
```

```
sage: w = words.ThueMorseWord()[:1000]
sage: [w.factor_complexity(i) for i in range(20)]
[1, 2, 4, 6, 10, 12, 16, 20, 22, 24, 28, 32, 36, 40, 42, 44, 46, 48, 52, 56]
```

factor_iterator(*n=None*)

Generate distinct factors of `self`.

INPUT:

- `n` – an integer, or `None`.

OUTPUT:

If `n` is an integer, returns an iterator over all distinct factors of length `n`. If `n` is `None`, returns an iterator generating all distinct factors.

EXAMPLES:

```
sage: w = Word('1213121')
sage: sorted( w.factor_iterator(0) )
[word: ]
sage: sorted( w.factor_iterator(10) )
[]
sage: sorted( w.factor_iterator(1) )
[word: 1, word: 2, word: 3]
sage: sorted( w.factor_iterator(4) )
[word: 1213, word: 1312, word: 2131, word: 3121]
sage: sorted( w.factor_iterator() )
[word: , word: 1, word: 12, word: 121, word: 1213, word: 12131, word: 121312,␣
↪word: 1213121, word: 13, word: 131, word: 1312, word: 13121, word: 2, word:␣
↪21, word: 213, word: 2131, word: 21312, word: 213121, word: 3, word: 31,␣
↪word: 312, word: 3121]
```

```
sage: u = Word([1,2,1,2,3])
sage: sorted( u.factor_iterator(0) )
[word: ]
sage: sorted( u.factor_iterator(10) )

sage: sorted( e.factor_iterator(17) )
[]
sage: sorted( e.factor_iterator() )
[word: ]
```

factor_occurrences_in(*other*)

Return an iterator over all occurrences (including overlapping ones) of `self` in `other` in their order of appearance.

Warning: This method is deprecated since 2020 and will be removed in a later version of SageMath. Use `factor_occurrences_iterator()` instead.

EXAMPLES:

```
sage: u = Word('121')
sage: w = Word('121213211213')
sage: list(u.factor_occurrences_in(w))
doctest:warning
...
DeprecationWarning: f.factor_occurrences_in(w) is deprecated.
Use w.factor_occurrences_iterator(f) instead.
See https://github.com/sagemath/sage/issues/30187 for details.
[0, 2, 8]
```

factor_set(*n=None*, *algorithm='suffix tree'*)

Return the set of factors (of length `n`) of `self`.

INPUT:

- `n` – an integer or `None` (default: `None`).
- `algorithm` – string (default: `'suffix tree'`), takes the following values:
  - `'suffix tree'` – construct and use the suffix tree of the word
  - `'naive'` – algorithm uses a sliding window

OUTPUT:

If `n` is an integer, returns the set of all distinct factors of length `n`. If `n` is `None`, returns the set of all distinct factors.

EXAMPLES:

```
sage: w = Word('121')
sage: sorted(w.factor_set())
[word: , word: 1, word: 12, word: 121, word: 2, word: 21]
sage: sorted(w.factor_set(algorithm='naive'))
[word: , word: 1, word: 12, word: 121, word: 2, word: 21]
```

```
sage: w = Word('1213121')
sage: for i in range(w.length()): sorted(w.factor_set(i))
[word: ]
[word: 1, word: 2, word: 3]
[word: 12, word: 13, word: 21, word: 31]
[word: 121, word: 131, word: 213, word: 312]
[word: 1213, word: 1312, word: 2131, word: 3121]
[word: 12131, word: 13121, word: 21312]
[word: 121312, word: 213121]
```

```
sage: w = Word([1,2,1,2,3])
sage: s = w.factor_set()
sage: sorted(s)
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123,␣
↪word: 2, word: 21, word: 212, word: 2123, word: 23, word: 3]
```

find(*sub*, *start=0*, *end=None*)

Return the index of the first occurrence of `sub` in `self`, such that `sub` is contained within `self[start:end]`. Return `-1` on failure.

INPUT:

- `sub` – string, list, tuple or word to search for.
- `start` – non-negative integer (default: `0`) specifying the position from which to start the search.
- `end` – non-negative integer (default: `None`) specifying the position at which the search must stop. If `None`, then the search is performed up to the end of the string.

OUTPUT:

a non-negative integer or `-1`

EXAMPLES:

```
sage: w = Word([0,1,0,0,1])
sage: w.find(Word([1,0]))
1
```

The `sub` argument can also be a tuple or a list:

```
sage: w.find([1,0])
1
sage: w.find((1,0))
1
```

Examples using `start` and `end`:

```
sage: w.find(Word([0,1]), start=1)
3
sage: w.find(Word([0,1]), start=1, end=5)
3
sage: w.find(Word([0,1]), start=1, end=4) == -1
True
sage: w.find(Word([1,1])) == -1
True
sage: w.find("aa")
-1
```

Instances of `Word_str` handle string inputs as well:

```
sage: w = Word('abac')
sage: w.find('a')
0
sage: w.find('ba')
1
```

first_pos_in(*other*)

Return the position of the first occurrence of `self` in `other`, or `None` if `self` is not a factor of `other`.

Warning: This method is deprecated since 2020 and will be removed in a later version of SageMath. Use `first_occurrence()` instead.

EXAMPLES:

```
sage: Word('12').first_pos_in(Word('131231'))
doctest:warning
...
DeprecationWarning: f.first_pos_in(w) is deprecated.
Use w.first_occurrence(f) instead.
See https://github.com/sagemath/sage/issues/30187 for details.
2
sage: Word('32').first_pos_in(Word('131231')) is None
True
```

foata_bijection()

Return word `self` under the Foata bijection.

The Foata bijection ϕ is a bijection on the set of words of given content (by a slight generalization of Section 2 in [FS1978]). It can be defined by induction on the size of the word: Given a word $w_1 w_2 \cdots w_n$, start with $\phi(w_1) = w_1$. At the i-th step, if $\phi(w_1 w_2 \cdots w_i) = v_1 v_2 \cdots v_i$, we define $\phi(w_1 w_2 \cdots w_i w_{i+1})$ by placing w_{i+1} on the end of the word $v_1 v_2 \cdots v_i$ and breaking the word up into blocks as follows. If $w_{i+1} \geq v_i$, place a vertical line to the right of each v_k for which $w_{i+1} \geq v_k$. Otherwise, if $w_{i+1} < v_i$, place a vertical line to the right of each v_k for which $w_{i+1} < v_k$. In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute $\phi([4, 1, 5, 4, 2, 2, 3])$, the sequence of words is

- 4,
- $|4|1 \to 41$,
- $|4|1|5 \to 415$,
- $|415|4 \to 5414$,
- $|5|4|14|2 \to 54412$,
- $|5441|2|2 \to 154422$,
- $|1|5442|2|3 \to 1254423$.

So $\phi([4, 1, 5, 4, 2, 2, 3]) = [1, 2, 5, 4, 4, 2, 3]$.

See also:

Foata bijection on Permutations.

EXAMPLES:

```
sage: w = Word([2,2,2,1,1,1])
sage: w.foata_bijection()
word: 112221
sage: w = Word([2,2,1,2,2,2,1,1,2,1])
sage: w.foata_bijection()
word: 2122212211
sage: w = Word([4,1,5,4,2,2,3])
sage: w.foata_bijection()
word: 1254423
```

good_suffix_table()

Return a table of the maximum skip you can do in order not to miss a possible occurrence of `self` in a word.

This is a part of the Boyer-Moore algorithm to find factors. See [BM1977].

EXAMPLES:

```
sage: Word('121321').good_suffix_table()
[5, 5, 5, 5, 3, 3, 1]
sage: Word('12412').good_suffix_table()
[3, 3, 3, 3, 3, 1]
```

has_period(*p*)

Return `True` if `self` has the period `p`, `False` otherwise.

Note: By convention, integers greater than the length of `self` are periods of `self`.

INPUT:

- `p` – an integer to check if it is a period of `self`.

EXAMPLES:

```
sage: w = Word('ababa')
sage: w.has_period(2)
True
sage: w.has_period(3)
False
sage: w.has_period(4)
True
sage: w.has_period(-1)
False
sage: w.has_period(5)
True
sage: w.has_period(6)
True
```

has_prefix(*other*)

Test whether `self` has `other` as a prefix.

INPUT:

- `other` – a word, or data describing a word

OUTPUT:

boolean

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: u = Word("abbab")
sage: w.has_prefix(u)
True
sage: u.has_prefix(w)
False
sage: u.has_prefix("abbab")
True
```

```
sage: w = Word([0,1,1,0,1,0,0,1,0,1,0,1,0])
sage: u = Word([0,1,1,0,1])
sage: w.has_prefix(u)
True
sage: u.has_prefix(w)
False
sage: u.has_prefix([0,1,1,0,1])
True
```

has_suffix(*other*)

Test whether `self` has `other` as a suffix.

Note: Some word datatype classes, like `WordDatatype_str`, override this method.

INPUT:

- `other` – a word, or data describing a word

OUTPUT:

boolean

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: u = Word("ababa")
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix("ababa")
True
```

```
sage: w = Word([0,1,1,0,1,0,0,1,0,1,0,1,0])
sage: u = Word([0,1,0,1,0])
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix([0,1,0,1,0])
True
```

implicit_suffix_tree()

Return the implicit suffix tree of `self`.

The *suffix tree* of a word w is a compactification of the suffix trie for w. The compactification removes all nodes that have exactly one incoming edge and exactly one outgoing edge. It consists of two components: a

tree and a word. Thus, instead of labelling the edges by factors of w, we can label them by indices of the occurrence of the factors in w.

Type `sage.combinat.words.suffix_trees.ImplicitSuffixTree?` for more information.

EXAMPLES:

```
sage: w = Word("cacao")
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: cacao
```

```
sage: w = Word([0,1,0,1,1])
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: 01011
```

inv_lex_less(*other*)

Return `True` if `self` is inverse lexicographically less than `other`.

EXAMPLES:

```
sage: Word([1,2,4]).inv_lex_less(Word([1,3,2]))
False
sage: Word([3,2,1]).inv_lex_less(Word([1,2,3]))
True
```

inversions()

Return a list of the inversions of `self`. An inversion is a pair (i, j) of non-negative integers $i < j$ such that `self[i] > self[j]`.

EXAMPLES:

```
sage: Word([1,2,3,2,2,1]).inversions()
[[1, 5], [2, 3], [2, 4], [2, 5], [3, 5], [4, 5]]
sage: Words([3,2,1])([1,2,3,2,2,1]).inversions()
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 2]]
sage: Word('abbaba').inversions()
[[1, 3], [1, 5], [2, 3], [2, 5], [4, 5]]
sage: Words('ba')('abbaba').inversions()
[[0, 1], [0, 2], [0, 4], [3, 4]]
```

is_balanced(*q=1*)

Return `True` if `self` is `q`-balanced, and `False` otherwise.

A finite or infinite word w is said to be *q-balanced* if for any two factors u, v of w of the same length, the difference between the number of x's in each of u and v is at most q for all letters x in the alphabet of w. A 1-balanced word is simply said to be balanced. See for instance [CFZ2000] and Chapter 2 of [Lot2002].

INPUT:

- `q` – integer (default: `1`), the balance level

OUTPUT:

boolean – the result

EXAMPLES:

```
sage: Word('1213121').is_balanced()
True
sage: Word('1122').is_balanced()
```

(continues on next page)

(continued from previous page)

```
False
sage: Word('121333121').is_balanced()
False
sage: Word('121333121').is_balanced(2)
False
sage: Word('121333121').is_balanced(3)
True
sage: Word('121122121').is_balanced()
False
sage: Word('121122121').is_balanced(2)
True
```

is_cadence(*seq*)

Return `True` if `seq` is a cadence of `self`, and `False` otherwise.

A *cadence* is an increasing sequence of indexes that all map to the same letter.

EXAMPLES:

```
sage: Word('121132123').is_cadence([0, 2, 6])
True
sage: Word('121132123').is_cadence([0, 1, 2])
False
sage: Word('121132123').is_cadence([])
True
```

is_christoffel()

Return `True` if `self` is a Christoffel word, and `False` otherwise.

The *Christoffel word* of slope p/q is obtained from the Cayley graph of $\mathbf{Z}/(p+q)\mathbf{Z}$ with generator q as follows. If $u \to v$ is an edge in the Cayley graph, then, $v = u + p \mod p + q$. Let a,`b` be the alphabet of w. Label the edge $u \to v$ by a if $u < v$ and b otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.

Equivalently, w is a Christoffel word iff w is a symmetric non-empty word and $w[1 : n-1]$ is a palindrome.

See for instance [Ber2007] and [BLRS2009].

INPUT:

- `self` – word

OUTPUT:

boolean – `True` if `self` is a Christoffel word, `False` otherwise.

EXAMPLES:

```
sage: Word('00100101').is_christoffel()
True
sage: Word('aab').is_christoffel()
True
sage: Word().is_christoffel()
False
sage: Word('123123123').is_christoffel()
False
sage: Word('00100').is_christoffel()
False
sage: Word('0').is_christoffel()
True
```

is_conjugate_with(*other*)

Return `True` if `self` is a conjugate of `other`, and `False` otherwise.

INPUT:

- `other` – a finite word

OUTPUT:

bool

EXAMPLES:

```
sage: w = Word([0..20])
sage: z = Word([7..20] + [0..6])
sage: w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20
sage: z
word: 7,8,9,10,11,12,13,14,15,16,17,18,19,20,0,1,2,3,4,5,6
sage: w.is_conjugate_with(z)
True
sage: z.is_conjugate_with(w)
True
sage: u = Word([4]*21)
sage: u.is_conjugate_with(w)
False
sage: u.is_conjugate_with(z)
False
```

Both words must be finite:

```
sage: w = Word(iter([2]*100),length='unknown')
sage: z = Word([2]*100)
sage: z.is_conjugate_with(w) #TODO: Not implemented for word of unknown length
True
sage: wf = Word(iter([2]*100),length='finite')
sage: z.is_conjugate_with(wf)
True
sage: wf.is_conjugate_with(z)
True
```

is_cube()

Return `True` if `self` is a cube, and `False` otherwise.

EXAMPLES:

```
sage: Word('012012012').is_cube()
True
sage: Word('01010101').is_cube()
False
sage: Word().is_cube()
True
sage: Word('012012').is_cube()
False
```

is_cube_free()

Return `True` if `self` does not contain cubes, and `False` otherwise.

EXAMPLES:

```
sage: Word('12312').is_cube_free()
True
sage: Word('32221').is_cube_free()
False
sage: Word().is_cube_free()
True
```

is_empty()

Return `True` if the length of `self` is zero, and `False` otherwise.

EXAMPLES:

```
sage: Word([]).is_empty()
True
sage: Word('a').is_empty()
False
```

is_factor(*other*)

Return `True` if `self` is a factor of `other`, and `False` otherwise.

A finite word $u \in A^*$ is a *factor* of a finite word $v \in A^*$ if there exists $p, s \in A^*$ such that $v = pus$.

EXAMPLES:

```
sage: u = Word('2113')
sage: w = Word('123121332131233121132123')
sage: u.is_factor(w)
True
sage: u = Word('321')
sage: w = Word('12312412313123123 12')
sage: u.is_factor(w)
False
```

The empty word is factor of another word:

```
sage: Word().is_factor(Word())
True
sage: Word().is_factor(Word('a'))
True
sage: Word().is_factor(Word([1,2,3]))
True
sage: Word().is_factor(Word(lambda n:n, length=5))
True
```

is_finite()

Return `True`.

EXAMPLES:

```
sage: Word([]).is_finite()
True
sage: Word('a').is_finite()
True
```

is_full(*f=None*)

Return `True` if `self` has defect 0, and `False` otherwise.

A word is *full* (or *rich*) if its defect is zero (see [BHNR2004]).

If `f` is given, then the `f`-palindromic defect is used (see [PeSt2011]).

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

boolean – If `f` is `None`, whether `self` is full; otherwise, whether `self` is full of `f`-palindromes.

EXAMPLES:

```
sage: words.ThueMorseWord()[:100].is_full()
False
sage: words.FibonacciWord()[:100].is_full()
True
sage: Word('000000000000000').is_full()
True
sage: Word('011010011001').is_full()
False
sage: Word('2194').is_full()
True
sage: Word().is_full()
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word().is_full(f)
True
sage: w = Word('ab')
sage: w.is_full()
True
sage: w.is_full(f)
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('abab').is_full(f)
True
sage: Word('abba').is_full(f)
False
```

A simple example of an infinite word full of f-palindromes:

```
sage: p = WordMorphism({0:'abc',1:'ab'})
sage: f = WordMorphism('a->b,b->a,c->c')
sage: p(words.FibonacciWord()[:50]).is_full(f)
True
sage: p(words.FibonacciWord()[:150]).is_full(f)
True
```

is_lyndon()

Return `True` if `self` is a Lyndon word, and `False` otherwise.

A *Lyndon word* is a non-empty word that is lexicographically smaller than each of its proper suffixes (for the given order on its alphabet). That is, w is a Lyndon word if w is non-empty and for each factorization $w = uv$ (with u, v both non-empty), we have $w < v$.

Equivalently, w is a Lyndon word iff w is a non-empty word that is lexicographically smaller than each of its proper conjugates for the given order on its alphabet.

See for instance [Lot1983].

EXAMPLES:

```
sage: Word('123132133').is_lyndon()
True
sage: Word().is_lyndon()
False
sage: Word('122112').is_lyndon()
False
```

is_overlap()

Return `True` if `self` is an overlap, and `False` otherwise.

EXAMPLES:

```
sage: Word('12121').is_overlap()
True
sage: Word('123').is_overlap()
False
sage: Word('1231').is_overlap()
False
sage: Word('123123').is_overlap()
False
sage: Word('1231231').is_overlap()
True
sage: Word().is_overlap()
False
```

is_palindrome(*f=None*)

Return `True` if `self` is a palindrome (or a `f`-palindrome), and `False` otherwise.

Let $f : \Sigma \to \Sigma$ be an involution that extends to a morphism on Σ^*. We say that $w \in \Sigma^*$ is a *`f`-palindrome* if $w = f(\tilde{w})$ [Lab2008]. Also called *`f`-pseudo-palindrome* [AZZ2005].

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. *WordMorphism*). The default value corresponds to usual palindromes, i.e., `f` equal to the identity.

EXAMPLES:

```
sage: Word('esope reste ici et se repose').is_palindrome()
False
sage: Word('esoperesteicietserepose').is_palindrome()
True
sage: Word('I saw I was I').is_palindrome()
True
sage: Word('abbcbba').is_palindrome()
True
sage: Word('abcbdba').is_palindrome()
False
```

Some f-palindromes:

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('aababb').is_palindrome(f)
True
```

```
sage: f = WordMorphism('a->b,b->a,c->c')
sage: Word('abacbacbab').is_palindrome(f)
True
```

```
sage: f = WordMorphism({'a':'b','b':'a'})
sage: Word('aababb').is_palindrome(f)
True
```

```
sage: f = WordMorphism({0:[1],1:[0]})
sage: w = words.ThueMorseWord()[:8]; w
word: 01101001
sage: w.is_palindrome(f)
True
```

The word must be in the domain of the involution:

```
sage: f = WordMorphism('a->a')
sage: Word('aababb').is_palindrome(f)
Traceback (most recent call last):
...
KeyError: 'b'
```

is_prefix(*other*)

Return `True` if `self` is a prefix of `other`, and `False` otherwise.

EXAMPLES:

```
sage: w = Word('0123456789')
sage: y = Word('012345')
sage: y.is_prefix(w)
True
sage: w.is_prefix(y)
False
sage: w.is_prefix(Word())
False
sage: Word().is_prefix(w)
True
sage: Word().is_prefix(Word())
True
```

is_primitive()

Return `True` if `self` is primitive, and `False` otherwise.

A finite word w is *primitive* if it is not a positive integer power of a shorter word.

EXAMPLES:

```
sage: Word('1231').is_primitive()
True
sage: Word('111').is_primitive()
False
```

is_proper_prefix(*other*)

Return `True` if `self` is a proper prefix of `other`, and `False` otherwise.

EXAMPLES:

```
sage: Word('12').is_proper_prefix(Word('123'))
True
sage: Word('12').is_proper_prefix(Word('12'))
False
sage: Word().is_proper_prefix(Word('123'))
True
sage: Word('123').is_proper_prefix(Word('12'))
False
sage: Word().is_proper_prefix(Word())
False
```

is_proper_suffix(*other*)

Return `True` if `self` is a proper suffix of `other`, and `False` otherwise.

EXAMPLES:

```
sage: Word('23').is_proper_suffix(Word('123'))
True
sage: Word('12').is_proper_suffix(Word('12'))
False
sage: Word().is_proper_suffix(Word('123'))
True
sage: Word('123').is_proper_suffix(Word('12'))
False
```

is_quasiperiodic()

Return `True` if `self` is quasiperiodic, and `False` otherwise.

A finite or infinite word w is *quasiperiodic* if it can be constructed by concatenations and superpositions of one of its proper factors u, which is called a *quasiperiod* of w. See for instance [AE1993], [Mar2004], and [GLR2008].

EXAMPLES:

```
sage: Word('abaababaabaababaaba').is_quasiperiodic()
True
sage: Word('abacaba').is_quasiperiodic()
False
sage: Word('a').is_quasiperiodic()
False
sage: Word().is_quasiperiodic()
False
sage: Word('abaaba').is_quasiperiodic()
True
```

is_rich(*f=None*)

Return `True` if `self` has defect 0, and `False` otherwise.

A word is *full* (or *rich*) if its defect is zero (see [BHNR2004]).

If `f` is given, then the `f`-palindromic defect is used (see [PeSt2011]).

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

boolean – If `f` is `None`, whether `self` is full; otherwise, whether `self` is full of `f`-palindromes.

EXAMPLES:

```
sage: words.ThueMorseWord()[:100].is_full()
False
sage: words.FibonacciWord()[:100].is_full()
True
sage: Word('0000000000000000').is_full()
True
sage: Word('011010011001').is_full()
False
sage: Word('2194').is_full()
True
sage: Word().is_full()
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word().is_full(f)
True
sage: w = Word('ab')
sage: w.is_full()
True
sage: w.is_full(f)
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('abab').is_full(f)
True
sage: Word('abba').is_full(f)
False
```

A simple example of an infinite word full of f-palindromes:

```
sage: p = WordMorphism({0:'abc',1:'ab'})
sage: f = WordMorphism('a->b,b->a,c->c')
sage: p(words.FibonacciWord()[:50]).is_full(f)
True
sage: p(words.FibonacciWord()[:150]).is_full(f)
True
```

is_smooth_prefix()

Return `True` if `self` is the prefix of a smooth word, and `False` otherwise.

Let $A_k = \{1, \ldots, k\}$, $k \geq 2$. An infinite word w in A_k^ω is said to be *smooth* if and only if for all positive integers m, $\Delta^m(w)$ is in A_k^ω, where $\Delta(w)$ is the word obtained from w by composing the length of consecutive runs of the same letter in w. See for instance [BL2003] and [BDLV2006].

INPUT:

- `self` – must be a word over the integers to get something other than `False`

OUTPUT:

boolean – whether `self` is a smooth prefix or not

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([1, 1, 2, 2, 1, 2, 1, 1]).is_smooth_prefix()
True
```

(continues on next page)

(continued from previous page)

```
sage: W([1, 2, 1, 2, 1, 2]).is_smooth_prefix()
False
```

is_square()

Return `True` if `self` is a square, and `False` otherwise.

EXAMPLES:

```
sage: Word([1,0,0,1]).is_square()
False
sage: Word('1212').is_square()
True
sage: Word('1213').is_square()
False
sage: Word('12123').is_square()
False
sage: Word().is_square()
True
```

is_square_free()

Return `True` if `self` does not contain squares, and `False` otherwise.

EXAMPLES:

```
sage: Word('12312').is_square_free()
True
sage: Word('31212').is_square_free()
False
sage: Word().is_square_free()
True
```

is_sturmian_factor()

Tell whether `self` is a factor of a Sturmian word.

The finite word `self` must be defined on a two-letter alphabet.

Equivalently, tells whether `self` is balanced. The advantage over the `is_balanced` method is that this one runs in linear time whereas `is_balanced` runs in quadratic time.

OUTPUT:

boolean – the result

EXAMPLES:

```
sage: w = Word('01110110110111101101',alphabet='01')
sage: w.is_sturmian_factor()
True
```

```
sage: words.LowerMechanicalWord(random(),alphabet='01')[:100].is_sturmian_
↪factor()
True
sage: words.CharacteristicSturmianWord(random())[:100].is_sturmian_factor()  ␣
↪          # needs sage.rings.real_mpfr
True
```

```
sage: w = Word('aabb',alphabet='ab')
sage: w.is_sturmian_factor()
False

sage: s1 = WordMorphism('a->ab,b->b')
sage: s2 = WordMorphism('a->ba,b->b')
sage: s3 = WordMorphism('a->a,b->ba')
sage: s4 = WordMorphism('a->a,b->ab')
sage: W = Words('ab')
sage: w = W('ab')
sage: for i in range(8): w = choice([s1,s2,s3,s4])(w)
sage: w.is_sturmian_factor()
True
```

Famous words:

```
sage: words.FibonacciWord()[:100].is_sturmian_factor()
True
sage: words.ThueMorseWord()[:1000].is_sturmian_factor()
False
sage: words.KolakoskiWord()[:1000].is_sturmian_factor()
False
```

See [Arn2002], [Ser1985], and [SU2009].

AUTHOR:

- Thierry Monteil

is_subword_of(*other*)

Return `True` if `self` is a subword of `other`, and `False` otherwise.

A finite word u is a *subword* of a finite word v if u is a subsequence of v. See Chapter 6 on Subwords in [Lot1997].

Some references define subword as a consecutive subsequence. Use *is_factor()* if this is what you need.

INPUT:

- `other` – a finite word

EXAMPLES:

```
sage: Word('bb').is_subword_of(Word('ababa'))
True
sage: Word('bbb').is_subword_of(Word('ababa'))
False
```

```
sage: Word().is_subword_of(Word('123'))
True
sage: Word('123').is_subword_of(Word('3211333213233321'))
True
sage: Word('321').is_subword_of(Word('111222121121221331112223332'))
False
```

See also:

longest_common_subword() number_of_subword_occurrences() is_factor()

is_suffix(*other*)

Return `True` if `self` is a suffix of `other`, and `False` otherwise.

EXAMPLES:

```
sage: w = Word('0123456789')
sage: y = Word('56789')
sage: y.is_suffix(w)
True
sage: w.is_suffix(y)
False
sage: Word('579').is_suffix(w)
False
sage: Word().is_suffix(y)
True
sage: w.is_suffix(Word())
False
sage: Word().is_suffix(Word())
True
```

is_symmetric(*f=None*)

Return `True` if `self` is symmetric (or `f`-symmetric), and `False` otherwise.

A word is *symmetric* (resp. *f-symmetric*) if it is the product of two palindromes (resp. f-palindromes). See [BHNR2004] and [DeLuca2006].

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

EXAMPLES:

```
sage: Word('abbabab').is_symmetric()
True
sage: Word('ababa').is_symmetric()
True
sage: Word('aababaabba').is_symmetric()
False
sage: Word('aabbbaababba').is_symmetric()
False
sage: f = WordMorphism('a->b,b->a')
sage: Word('aabbbaababba').is_symmetric(f)
True
```

is_tangent()

Tell whether `self` is a tangent word.

The finite word `self` must be defined on a two-letter alphabet.

A binary word is said to be *tangent* if it can appear in infinitely many cutting sequences of a smooth curve, where each cutting sequence is observed on a progressively smaller grid.

This class of words strictly contains the class of 1-balanced words, and is strictly contained in the class of 2-balanced words.

This method runs in linear time.

OUTPUT:

boolean – the result

EXAMPLES:

```
sage: w = Word('01110110110111011101',alphabet='01')
sage: w.is_tangent()
True
```

Some tangent words may not be balanced:

```
sage: Word('aabb',alphabet='ab').is_balanced()
False
sage: Word('aabb',alphabet='ab').is_tangent()
True
```

Some 2-balanced words may not be tangent:

```
sage: Word('aaabb',alphabet='ab').is_tangent()
False
sage: Word('aaabb',alphabet='ab').is_balanced(2)
True
```

Famous words:

```
sage: words.FibonacciWord()[:100].is_tangent()
True
sage: words.ThueMorseWord()[:1000].is_tangent()
True
sage: words.KolakoskiWord()[:1000].is_tangent()
False
```

See [Mon2010].

AUTHOR:

- Thierry Monteil

is_yamanouchi(*n=None*)

Return whether `self` is Yamanouchi.

A word w is Yamanouchi if, when read from right to left, it always has weakly more i's than $i+1$'s for all i that appear in w.

INPUT:

- `n` – (optional) an integer specifying the maximal letter in the alphabet

EXAMPLES:

```
sage: w = Word([1,2,4,3,2,2,2])
sage: w.is_yamanouchi()
False
sage: w = Word([2,3,4,3,1,2,1,1,2,1])
sage: w.is_yamanouchi()
True
sage: w = Word([3,1])
sage: w.is_yamanouchi(n=3)
False
sage: w.is_yamanouchi()
True
sage: w = Word([3,1],alphabet=[1,2,3])
sage: w.is_yamanouchi()
```

(continues on next page)

(continued from previous page)

```
False
sage: w = Word([2,1,1,2])
sage: w.is_yamanouchi()
False
```

iterated_left_palindromic_closure(*f=None*)

Return the iterated left (f-)palindromic closure of self.

INPUT:

- f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).

OUTPUT:

word – the left iterated f-palindromic closure of self.

EXAMPLES:

```
sage: Word('123').iterated_left_palindromic_closure()
word: 3231323
sage: f = WordMorphism('a->b,b->a')
sage: Word('ab').iterated_left_palindromic_closure(f=f)
word: abbaab
sage: Word('aab').iterated_left_palindromic_closure(f=f)
word: abbaabbaab
```

lacunas(*f=None*)

Return the list of all the lacunas of self.

A *lacuna* is a position in a word where the longest (*f*-)palindromic suffix is not unioccurrent (see [BMBL2008]).

INPUT:

- f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism). The default value corresponds to usual palindromes, i.e., f equal to the identity.

OUTPUT:

a list – list of all the lacunas of self

EXAMPLES:

```
sage: w = Word([0,1,1,2,3,4,5,1,13,3])
sage: w.lacunas()
[7, 9]
sage: words.ThueMorseWord()[:100].lacunas()
[8, 9, 24, 25, 32, 33, 34, 35, 36, 37, 38, 39, 96, 97, 98, 99]
sage: f = WordMorphism({0:[1],1:[0]})
sage: words.ThueMorseWord()[:50].lacunas(f)
[0, 2, 4, 12, 16, 17, 18, 19, 48, 49]
```

last_position_dict()

Return a dictionary that contains the last position of each letter in self.

EXAMPLES:

```
sage: Word('1231232').last_position_dict()
{'1': 3, '2': 6, '3': 5}
```

left_special_factors(*n=None*)

Return the left special factors (of length `n`).

A factor u of a word w is *left special* if there are two distinct letters a and b such that au and bu are factors of w.

INPUT:

- `n` – integer (default: `None`). If `None`, it returns all left special factors.

OUTPUT:

a list of words

EXAMPLES:

```
sage: alpha, beta, x = 0.54, 0.294, 0.1415
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: for i in range(5):
....:     print("{} {}".format(i, sorted(w.left_special_factors(i))))
0 [word: ]
1 [word: 0]
2 [word: 00, word: 01]
3 [word: 000, word: 010]
4 [word: 0000, word: 0101]
```

left_special_factors_iterator(*n=None*)

Return an iterator over the left special factors (of length `n`).

A factor u of a word w is *left special* if there are two distinct letters a and b such that au and bu are factors of w.

INPUT:

- `n` – integer (default: `None`). If `None`, it returns an iterator over all left special factors.

EXAMPLES:

```
sage: alpha, beta, x = 0.54, 0.294, 0.1415
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: sorted(w.left_special_factors_iterator(3))
[word: 000, word: 010]
sage: sorted(w.left_special_factors_iterator(4))
[word: 0000, word: 0101]
sage: sorted(w.left_special_factors_iterator(5))
[word: 00000, word: 01010]
```

length()

Return the length of `self`.

length_border()

Return the length of the border of `self`.

The *border* of a word is the longest word that is both a proper prefix and a proper suffix of `self`.

EXAMPLES:

```
sage: Word('121').length_border()
1
sage: Word('1').length_border()
0
```

(continues on next page)

(continued from previous page)

```
sage: Word('1212').length_border()
2
sage: Word('111').length_border()
2
sage: Word().length_border() is None
True
```

length_maximal_palindrome(*j*, *m=None*, *f=None*)

Return the length of the longest palindrome centered at position `j`.

INPUT:

- `j` – rational, position of the symmetry axis of the palindrome. Must return an integer when doubled. It is an integer when the center of the palindrome is a letter.
- `m` – integer (default: `None`), minimal length of palindrome, if known. The parity of `m` can't be the same as the parity of `2j`.
- `f` – involution (default: `None`), on the alphabet. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

length of the longest `f`-palindrome centered at position `j`

EXAMPLES:

```
sage: Word('01001010').length_maximal_palindrome(3/2)
0
sage: Word('01101001').length_maximal_palindrome(3/2)
4
sage: Word('01010').length_maximal_palindrome(j=3, f='0->1,1->0')
0
sage: Word('01010').length_maximal_palindrome(j=2.5, f='0->1,1->0')
4
sage: Word('0222220').length_maximal_palindrome(3, f='0->1,1->0,2->2')
5
```

```
sage: w = Word('abcdcbaxyzzyx')
sage: w.length_maximal_palindrome(3)
7
sage: w.length_maximal_palindrome(3, 3)
7
sage: w.length_maximal_palindrome(3.5)
0
sage: w.length_maximal_palindrome(9.5)
6
sage: w.length_maximal_palindrome(9.5, 2)
6
```

lengths_maximal_palindromes(*f=None*)

Return the length of maximal palindromes centered at each position.

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a list – The length of the maximal palindrome (or `f`-palindrome) with a given symmetry axis (letter or space between two letters).

EXAMPLES:

```
sage: Word('01101001').lengths_maximal_palindromes()
[0, 1, 0, 1, 4, 1, 0, 3, 0, 3, 0, 1, 4, 1, 0, 1, 0]
sage: Word('00000').lengths_maximal_palindromes()
[0, 1, 2, 3, 4, 5, 4, 3, 2, 1, 0]
sage: Word('0').lengths_maximal_palindromes()
[0, 1, 0]
sage: Word('').lengths_maximal_palindromes()
[0]
sage: Word().lengths_maximal_palindromes()
[0]
sage: f = WordMorphism('a->b,b->a')
sage: Word('abbabaab').lengths_maximal_palindromes(f)
[0, 0, 2, 0, 0, 0, 2, 0, 8, 0, 2, 0, 0, 0, 2, 0, 0]
```

lengths_unioccurrent_lps(*f=None*)

Return the list of the lengths of the unioccurrent longest (`f`)-palindromic suffixes (lps) for each non-empty prefix of `self`. No unioccurrent lps are indicated by `None`.

It corresponds to the function H_w defined in [BMBL2008] and [BMBFLR2008].

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`). The default value corresponds to usual palindromes, i.e., `f` equal to the identity.

OUTPUT:

a list – list of the length of the unioccurrent longest palindromic suffix (lps) for each non-empty prefix of `self`. No unioccurrent lps are indicated by `None`.

EXAMPLES:

```
sage: w = Word([0,1,1,2,3,4,5,1,13,3])
sage: w.lengths_unioccurrent_lps()
[1, 1, 2, 1, 1, 1, 1, None, 1, None]
sage: f = words.FibonacciWord()[:20]
sage: f.lengths_unioccurrent_lps() == f.lps_lengths()[1:]
True
sage: t = words.ThueMorseWord()
sage: t[:20].lengths_unioccurrent_lps()
[1, 1, 2, 4, 3, 3, 2, 4, None, None, 6, 8, 10, 12, 14, 16, 6, 8, 10, 12]
sage: f = WordMorphism({1:[0],0:[1]})
sage: t[:15].lengths_unioccurrent_lps(f)
[None, 2, None, 2, None, 4, 6, 8, 4, 6, 4, 6, None, 4, 6]
```

letters()

Return the list of letters that appear in this word, listed in the order of first appearance.

EXAMPLES:

```
sage: Word([0,1,1,0,1,0,0,1]).letters()
[0, 1]
sage: Word("cacao").letters()
['c', 'a', 'o']
```

longest_backward_extension(*x*, *y*)

Compute the length of the longest factor of `self` that ends at `x` and that matches a factor that ends at `y`.

INPUT:

- `x`, `y` – positions in `self`

EXAMPLES:

```
sage: w = Word('0011001')
sage: w.longest_backward_extension(6, 2)
3
sage: w.longest_backward_extension(1, 4)
1
sage: w.longest_backward_extension(1, 3)
0
```

The method also accepts negative positions indicating the distance from the end of the word (in order to be consist with how negative indices work with lists). For instance, for a word of length 7, using positions 6 and -5 is the same as using positions 6 and 2:

```
sage: w.longest_backward_extension(6, -5)
3
sage: w.longest_backward_extension(-6, 4)
1
```

longest_common_subword(*other*)

Return a longest subword of `self` and `other`.

A subword of a word is a subset of the word's letters, read in the order in which they appear in the word.

For more information, see Wikipedia article Longest_common_subsequence_problem.

INPUT:

- `other` – a word

ALGORITHM:

For any indices i, j, we compute the longest common subword `lcs[i,j]` of `self[:i]` and `other[:j]`. This can be easily obtained as the longest of

- `lcs[i-1,j]`
- `lcs[i,j-1]`
- `lcs[i-1,j-1]+self[i]` if `self[i]==other[j]`

EXAMPLES:

```
sage: v1 = Word("abc")
sage: v2 = Word("ace")
sage: v1.longest_common_subword(v2)
word: ac

sage: w1 = Word("10101010101010101010101010101010101010101010")
sage: w2 = Word("00110011001100110011001100110011001100110011")
sage: w1.longest_common_subword(w2)
word: 00110011001100110011010101010
```

See also:

is_subword_of()

longest_common_suffix(*other*)

Return the longest common suffix of `self` and `other`.

EXAMPLES:

```
sage: w = Word('112345678')
sage: u = Word('1115678')
sage: w.longest_common_suffix(u)
word: 5678
sage: u.longest_common_suffix(u)
word: 1115678
sage: u.longest_common_suffix(w)
word: 5678
sage: w.longest_common_suffix(w)
word: 112345678
sage: y = Word('549332345')
sage: w.longest_common_suffix(y)
word:
```

longest_forward_extension(*x*, *y*)

Compute the length of the longest factor of `self` that starts at `x` and that matches a factor that starts at `y`.

INPUT:

- `x`, `y` – positions in `self`

EXAMPLES:

```
sage: w = Word('0011001')
sage: w.longest_forward_extension(0, 4)
3
sage: w.longest_forward_extension(0, 2)
0
```

The method also accepts negative positions indicating the distance from the end of the word (in order to be consist with how negative indices work with lists). For instance, for a word of length 7, using positions -3 and 2 is the same as using positions 4 and 2:

```
sage: w.longest_forward_extension(1, -2)
2
sage: w.longest_forward_extension(4, -3)
3
```

lps(*f=None*, *l=None*)

Return the longest palindromic (or `f`-palindromic) suffix of `self`.

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).
- `l` – integer (default: `None`) the length of the longest palindrome suffix of ``self[:-1]``, if known.

OUTPUT:

word – If `f` is `None`, the longest palindromic suffix of `self`; otherwise, the longest `f`-palindromic suffix of `self`.

EXAMPLES:

```
sage: Word('0111').lps()
word: 111
sage: Word('011101').lps()
word: 101
sage: Word('6667').lps()
word: 7
sage: Word('abbabaab').lps()
word: baab
sage: Word().lps()
word:
sage: f = WordMorphism('a->b,b->a')
sage: Word('abbabaab').lps(f=f)
word: abbabaab
sage: w = Word('33412321')
sage: w.lps(l=3)
word: 12321
sage: Y = Word
sage: w = Y('01101001')
sage: w.lps(l=2)
word: 1001
sage: w.lps()
word: 1001
sage: w.lps(l=None)
word: 1001
sage: Y().lps(l=2)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: v = Word('abbabaab')
sage: pal = v[:0]
sage: for i in range(1, v.length()+1):
....:   pal = v[:i].lps(l=pal.length())
....:   pal
word: a
word: b
word: bb
word: abba
word: bab
word: aba
word: aa
word: baab
sage: f = WordMorphism('a->b,b->a')
sage: v = Word('abbabaab')
sage: pal = v[:0]
sage: for i in range(1, v.length()+1):
....:   pal = v[:i].lps(f=f, l=pal.length())
....:   pal
word:
word: ab
word:
word: ba
word: ab
word: baba
word: bbabaa
word: abbabaab
```

lps_lengths (*f=None*)

Return the length of the longest palindromic suffix of each prefix.

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a list – The length of the longest palindromic (or `f`-palindromic) suffix of each prefix of `self`.

EXAMPLES:

```
sage: Word('01101001').lps_lengths()
[0, 1, 1, 2, 4, 3, 3, 2, 4]
sage: Word('00000').lps_lengths()
[0, 1, 2, 3, 4, 5]
sage: Word('0').lps_lengths()
[0, 1]
sage: Word('').lps_lengths()
[0]
sage: Word().lps_lengths()
[0]
sage: f = WordMorphism('a->b,b->a')
sage: Word('abbabaab').lps_lengths(f)
[0, 0, 2, 0, 2, 2, 4, 6, 8]
```

lyndon_factorization()

Return the Lyndon factorization of `self`.

The *Lyndon factorization* of a finite word w is the unique factorization of w as a non-increasing product of Lyndon words, i.e., $w = l_1 \cdots l_n$ where each l_i is a Lyndon word and $l_1 \geq \cdots \geq l_n$. See for instance [Duv1983].

OUTPUT:

the list $[l_1, \ldots, l_n]$ of factors obtained

EXAMPLES:

```
sage: Word('010010010001000').lyndon_factorization()
(01, 001, 001, 0001, 0, 0, 0)
sage: Words('10')('010010010001000').lyndon_factorization()
(0, 10010010001000)
sage: Word('abbababbaababba').lyndon_factorization()
(abb, ababb, aababb, a)
sage: Words('ba')('abbababbaababba').lyndon_factorization()
(a, bbababbaaba, bba)
sage: Word([1,2,1,3,1,2,1]).lyndon_factorization()
(1213, 12, 1)
```

major_index(*final_descent=False*)

Return the major index of `self`.

The major index of a word w is the sum of the descents of w.

With the `final_descent` option, the last position of a non-empty word is also considered as a descent.

See also:

major index on Permutations.

EXAMPLES:

```
sage: w = Word([2,1,3,3,2])
sage: w.major_index()
5
sage: w = Word([2,1,3,3,2])
sage: w.major_index(final_descent=True)
10
```

minimal_conjugate()

Return the lexicographically minimal conjugate of this word (see Wikipedia article Lexicographically_minimal_string_rotation).

EXAMPLES:

```
sage: Word('213').minimal_conjugate()
word: 132
sage: Word('11').minimal_conjugate()
word: 11
sage: Word('12112').minimal_conjugate()
word: 11212
sage: Word('211').minimal_conjugate()
word: 112
sage: Word('211211211').minimal_conjugate()
word: 112112112
```

minimal_period()

Return the period of `self`.

Let A be an alphabet. An integer $p \geq 1$ is a *period* of a word $w = a_1 a_2 \cdots a_n$ where $a_i \in A$ if $a_i = a_{i+p}$ for $i = 1, \ldots, n-p$. The smallest period of w is called *the* period of w. See Chapter 1 of [Lot2002].

EXAMPLES:

```
sage: Word('aba').minimal_period()
2
sage: Word('abab').minimal_period()
2
sage: Word('ababa').minimal_period()
2
sage: Word('ababaa').minimal_period()
5
sage: Word('ababac').minimal_period()
6
sage: Word('aaaaaa').minimal_period()
1
sage: Word('a').minimal_period()
1
sage: Word().minimal_period()
1
```

nb_factor_occurrences_in(*other*)

Return the number of times `self` appears as a factor in `other`.

Warning: This method is deprecated since 2020 and will be removed in a later version of SageMath. Use *number_of_factor_occurrences()* instead.

EXAMPLES:

```
sage: Word('123').nb_factor_occurrences_in(Word('112332312313112332121123'))
doctest:warning
...
DeprecationWarning: f.nb_factor_occurrences_in(w) is deprecated.
Use w.number_of_factor_occurrences(f) instead.
See https://github.com/sagemath/sage/issues/30187 for details.
4
sage: Word('321').nb_factor_occurrences_in(Word('112332312313112332221123'))
0
```

An error is raised for the empty word:

```
sage: Word().nb_factor_occurrences_in(Word('123'))
Traceback (most recent call last):
...
NotImplementedError: The factor must be non empty
```

nb_subword_occurrences_in(*other*)

Return the number of times `self` appears in `other` as a subword.

This corresponds to the notion of $binomial coefficient$ of two finite words whose properties are presented in the chapter of Lothaire's book written by Sakarovitch and Simon [Lot1997].

Warning: This method is deprecated since 2020 and will be removed in a later version of SageMath. Use *number_of_subword_occurrences()* instead.

INPUT:

- `other` – finite word

EXAMPLES:

```
sage: tm = words.ThueMorseWord()

sage: u = Word([0,1,0,1])
sage: u.nb_subword_occurrences_in(tm[:1000])
doctest:warning
...
DeprecationWarning: f.nb_subword_occurrences_in(w) is deprecated.
Use w.number_of_subword_occurrences(f) instead.
See https://github.com/sagemath/sage/issues/30187 for details.
2604124996

sage: u = Word([0,1,0,1,1,0])
sage: u.nb_subword_occurrences_in(tm[:100])
20370432
```

Note: This code, based on [MSSY2001], actually compute the number of occurrences of all prefixes of `self` as subwords in all prefixes of `other`. In particular, its complexity is bounded by `len(self) * len(other)`.

number_of_factor_occurrences(*other*)

Return the number of times `other` appears as a factor in `self`.

INPUT:

- `other` – a non empty word

EXAMPLES:

```
sage: w = Word('112332312313112332121123')
sage: w.number_of_factor_occurrences(Word('123'))
4
sage: w = Word('112332312313112332221123')
sage: w.number_of_factor_occurrences(Word('321'))
0
```

```
sage: Word().number_of_factor_occurrences(Word('123'))
0
```

An error is raised for the empty word:

```
sage: Word('123').number_of_factor_occurrences(Word())
Traceback (most recent call last):
...
NotImplementedError: The factor must be non empty
```

number_of_factors (*n=None*, *algorithm='suffix tree'*)

Count the number of distinct factors of `self`.

INPUT:

- `n` – an integer, or `None`.
- `algorithm` – string (default: `'suffix tree'`), takes the following values:
  - `'suffix tree'` – construct and use the suffix tree of the word
  - `'naive'` – algorithm uses a sliding window

OUTPUT:

If `n` is an integer, returns the number of distinct factors of length `n`. If `n` is `None`, returns the total number of distinct factors.

EXAMPLES:

```
sage: w = Word([1,2,1,2,3])
sage: w.number_of_factors()
13
sage: [w.number_of_factors(i) for i in range(6)]
[1, 3, 3, 3, 2, 1]
```

```
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_factors(i) for i in range(10)]
[1, 2, 4, 6, 10, 12, 16, 20, 22, 24]
```

```
sage: Word('1213121').number_of_factors()
22
sage: Word('1213121').number_of_factors(1)
3
```

```
sage: Word('a'*100).number_of_factors()
101
sage: Word('a'*100).number_of_factors(77)
1
```

```
sage: Word().number_of_factors()
1
sage: Word().number_of_factors(17)
0
```

```
sage: blueberry = Word("blueberry")
sage: blueberry.number_of_factors()
43
sage: [blueberry.number_of_factors(i) for i in range(10)]
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]
```

number_of_inversions()

Return the number of inversions in `self`.

An inversion of a word $w = w_1 \dots w_n$ is a pair of indices (i, j) with $i < j$ and $w_i > w_j$.

See also:

number of inversions on Permutations.

EXAMPLES:

```
sage: w = Word([2,1,3,3,2])
sage: w.number_of_inversions()
3
```

number_of_left_special_factors(n)

Return the number of left special factors of length `n`.

A factor u of a word w is *left special* if there are two distinct letters a and b such that au and bu are factors of w.

INPUT:

- `n` – integer

OUTPUT:

a non-negative integer

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.number_of_left_special_factors(i) for i in range(10)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

```
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_left_special_factors(i) for i in range(10)]
[1, 2, 2, 4, 2, 4, 4, 2, 2, 4]
```

number_of_letter_occurrences(*letter*)

Return the number of occurrences of `letter` in `self`.

INPUT:

- `letter` – a letter

OUTPUT:

- integer

EXAMPLES:

```
sage: w = Word('abbabaab')
sage: w.number_of_letter_occurrences('a')
4
sage: w.number_of_letter_occurrences('ab')
0
```

This methods is equivalent to `list(w).count(letter)` and `tuple(w).count(letter)`, thus `count` is an alias for the method `number_of_letter_occurrences`:

```
sage: list(w).count('a')
4
sage: w.count('a')
4
```

But notice that if `s` and `w` are strings, `Word(s).count(w)` counts the number occurrences of `w` as a letter in `Word(s)` which is not the same as `s.count(w)` which counts the number of occurrences of the string `w` inside `s`:

```
sage: s = 'abbabaab'
sage: s.count('ab')
3
sage: Word(s).count('ab')
0
```

See also:

sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()

number_of_right_special_factors(*n*)

Return the number of right special factors of length `n`.

A factor u of a word w is *right special* if there are two distinct letters a and b such that ua and ub are factors of w.

INPUT:

- `n` – integer

OUTPUT:

a non-negative integer

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.number_of_right_special_factors(i) for i in range(10)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

```
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_right_special_factors(i) for i in range(10)]
[1, 2, 2, 4, 2, 4, 4, 2, 2, 4]
```

number_of_subword_occurrences(*other*)

Return the number of times `other` appears in `self` as a subword.

This corresponds to the notion of $binomial coefficient$ of two finite words whose properties are presented in the chapter of Lothaire's book written by Sakarovitch and Simon [Lot1997].

INPUT:

- `other` – finite word

EXAMPLES:

```
sage: tm = words.ThueMorseWord()
sage: u = Word([0,1,0,1])
sage: tm[:1000].number_of_subword_occurrences(u)
2604124996

sage: u = Word([0,1,0,1,1,0])
sage: tm[:100].number_of_subword_occurrences(u)
20370432
```

Note: This code, based on [MSSY2001], actually compute the number of occurrences of all prefixes of `self` as subwords in all prefixes of `other`. In particular, its complexity is bounded by `len(self) * len(other)`.

order()

Return the order of `self`.

Let $p(w)$ be the period of a word w. The positive rational number $|w|/p(w)$ is the *order* of w. See Chapter 8 of [Lot2002].

OUTPUT:

rational – the order

EXAMPLES:

```
sage: Word('abaaba').order()
2
sage: Word('ababaaba').order()
8/5
sage: Word('a').order()
1
sage: Word('aa').order()
2
sage: Word().order()
0
```

overlap_partition(*other*, *delay=0*, *p=None*, *involution=None*)

Return the partition of the alphabet induced by the overlap of `self` and `other` with the given `delay`.

The partition of the alphabet is given by the equivalence relation obtained from the symmetric, reflexive and transitive closure of the set of pairs of letters $R_{u,v,d} = \{(u_k, v_{k-d}) : 0 \leq k < n, 0 \leq k - d < m\}$ where $u = u_0u_1 \cdots u_{n-1}$, $v = v_0v_1 \cdots v_{m-1}$ are two words on the alphabet A and d is an integer.

The equivalence relation defined by R is inspired from [Lab2008].

INPUT:

- `other` – word on the same alphabet as `self`
- `delay` – integer (default: `0`)
- `p` – disjoint sets data structure (default: `None`), a partition of the alphabet into disjoint sets to start with. If `None`, each letter start in distinct equivalence classes.
- `involution` – callable (default: `None`), an involution on the alphabet. If `involution` is not `None`, the relation $R_{u,v,d} \cup R_{involution(u),involution(v),d}$ is considered.

OUTPUT:

a disjoint set data structure

EXAMPLES:

```
sage: W = Words(list('abc012345'))
sage: u = W('abc')
sage: v = W('01234')
sage: u.overlap_partition(v)
{{'0', 'a'}, {'1', 'b'}, {'2', 'c'}, {'3'}, {'4'}, {'5'}}
sage: u.overlap_partition(v, 2)
{{'0', 'c'}, {'1'}, {'2'}, {'3'}, {'4'}, {'5'}, {'a'}, {'b'}}
sage: u.overlap_partition(v, -1)
{{'0'}, {'1', 'a'}, {'2', 'b'}, {'3', 'c'}, {'4'}, {'5'}}
```

You can re-use the same disjoint set and do more than one overlap:

```
sage: p = u.overlap_partition(v, 2)
sage: p
{{'0', 'c'}, {'1'}, {'2'}, {'3'}, {'4'}, {'5'}, {'a'}, {'b'}}
sage: u.overlap_partition(v, 1, p)
{{'0', '1', 'b', 'c'}, {'2'}, {'3'}, {'4'}, {'5'}, {'a'}}
```

The function `overlap_partition` can be used to study equations on words. For example, if a word w overlaps itself with delay d, then d is a period of w:

```
sage: W = Words(range(20))
sage: w = W(range(14)); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13
sage: d = 5
sage: p = w.overlap_partition(w, d)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 56789567895678
sage: w2.minimal_period() == d
True
```

If a word is equal to its reversal, then it is a palindrome:

```
sage: W = Words(range(20))
sage: w = W(range(17)); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16
sage: p = w.overlap_partition(w.reversal(), 0)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 01234567876543210
sage: w2.parent()
Finite words over {0, 1, 2, 3, 4, 5, 6, 7, 8, 17, 18, 19}
sage: w2.is_palindrome()
True
```

If the reversal of a word w is factor of its square w^2, then w is symmetric, i.e. the product of two palindromes:

```
sage: W = Words(range(10))
sage: w = W(range(10)); w
word: 0123456789
sage: p = (w*w).overlap_partition(w.reversal(), 4)
sage: m = WordMorphism(p.element_to_root_dict())
```

(continues on next page)

(continued from previous page)

```
sage: w2 = m(w); w2
word: 0110456654
sage: w2.is_symmetric()
True
```

If the image of the reversal of a word w under an involution f is factor of its square w^2, then w is f-symmetric:

```
sage: W = Words([-11,-9,..,11])
sage: w = W([1,3,..,11])
sage: w
word: 1,3,5,7,9,11
sage: inv = lambda x:-x
sage: f = WordMorphism(dict( (a, inv(a)) for a in W.alphabet()))
sage: p = (w*w).overlap_partition(f(w).reversal(), 2, involution=f)
sage: m = WordMorphism(p.element_to_root_dict())
sage: m(w)
word: 1,-1,5,7,-7,-5
sage: m(w).is_symmetric(f)
True
```

palindrome_prefixes()

Return a list of all palindrome prefixes of `self`.

OUTPUT:

a list – A list of all palindrome prefixes of `self`.

EXAMPLES:

```
sage: w = Word('abaaba')
sage: w.palindrome_prefixes()
[word: , word: a, word: aba, word: abaaba]
sage: w = Word('abbbbbbbbbb')
sage: w.palindrome_prefixes()
[word: , word: a]
```

palindromes(*f=None*)

Return the set of all palindromic (or `f`-palindromic) factors of `self`.

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a set – If `f` is `None`, the set of all palindromic factors of `self`; otherwise, the set of all `f`-palindromic factors of `self`.

EXAMPLES:

```
sage: sorted(Word('01101001').palindromes())
[word: , word: 0, word: 00, word: 010, word: 0110, word: 1, word: 1001, word:␣
↪101, word: 11]
sage: sorted(Word('00000').palindromes())
[word: , word: 0, word: 00, word: 000, word: 0000, word: 00000]
sage: sorted(Word('0').palindromes())
[word: , word: 0]
sage: sorted(Word('').palindromes())
```

(continues on next page)

(continued from previous page)

```
[word: ]
sage: sorted(Word().palindromes())
[word: ]
sage: f = WordMorphism('a->b,b->a')
sage: sorted(Word('abbabaab').palindromes(f))
[word: , word: ab, word: abbabaab, word: ba, word: baba, word: bbabaa]
```

palindromic_closure(*side='right'*, *f=None*)

Return the shortest palindrome having `self` as a prefix (or as a suffix if `side` is `'left'`).

See [DeLuca2006].

INPUT:

- `side` – `'right'` or `'left'` (default: `'right'`) the direction of the closure
- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a word – If `f` is `None`, the right palindromic closure of `self`; otherwise, the right `f`-palindromic closure of `self`. If `side` is `'left'`, the left palindromic closure.

EXAMPLES:

```
sage: Word('1233').palindromic_closure()
word: 123321
sage: Word('12332').palindromic_closure()
word: 123321
sage: Word('0110343').palindromic_closure()
word: 01103430110
sage: Word('0110343').palindromic_closure(side='left')
word: 3430110343
sage: Word('01105678').palindromic_closure(side='left')
word: 876501105678
sage: w = Word('abbaba')
sage: w.palindromic_closure()
word: abbababba
```

```
sage: f = WordMorphism('a->b,b->a')
sage: w.palindromic_closure(f=f)
word: abbabaab
sage: w.palindromic_closure(f=f, side='left')
word: babaabbaba
```

palindromic_complexity(*n*)

Return the number of distinct palindromic factors of length `n` of `self`.

INPUT:

- `n` – the length of the factors.

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.palindromic_complexity(i) for i in range(20)]
[1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2]
```

```
sage: w = words.ThueMorseWord()[:1000]
sage: [w.palindromic_complexity(i) for i in range(20)]
[1, 2, 2, 2, 2, 0, 4, 0, 4, 0, 4, 0, 4, 0, 2, 0, 2, 0, 4, 0]
```

palindromic_lacunas_study(*f=None*)

Return interesting statistics about longest (f-)palindromic suffixes and lacunas of self (see [BMBL2008] and [BMBFLR2008]).

Note that a word w has at most $|w|+1$ different palindromic factors (see [DJP2001]). For f-palindromes (or pseudopalindromes or theta-palindromes), the maximum number of f-palindromic factors is $|w|+1-g_f(w)$, where $g_f(w)$ is the number of pairs $\{a, f(a)\}$ such that a is a letter, a is not equal to $f(a)$, and a or $f(a)$ occurs in w, see [Star2011].

INPUT:

- f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism). The default value corresponds to usual palindromes, i.e., f equal to the identity.

OUTPUT:

- list – list of the length of the longest palindromic suffix (lps) for each non-empty prefix of self
- list – list of all the lacunas, i.e. positions where there is no unioccurrent lps
- set – set of palindromic factors of self

EXAMPLES:

```
sage: a,b,c = Word('abbabaabbaab').palindromic_lacunas_study()
sage: a
[1, 1, 2, 4, 3, 3, 2, 4, 2, 4, 6, 8]
sage: b
[8, 9]
sage: c           # random order
set([word: , word: b, word: bab, word: abba, word: bb, word: aa, word:␣
↪baabbaab, word: baab, word: aba, word: aabbaa, word: a])
```

```
sage: f = WordMorphism('a->b,b->a')
sage: a,b,c = Word('abbabaab').palindromic_lacunas_study(f=f)
sage: a
[0, 2, 0, 2, 2, 4, 6, 8]
sage: b
[0, 2, 4]
sage: c            # random order
set([word: , word: ba, word: baba, word: ab, word: bbabaa, word: abbabaab])
sage: c == set([Word(), Word('ba'), Word('baba'), Word('ab'), Word('bbabaa'),␣
↪Word('abbabaab')])
True
```

periods(*divide_length=False*)

Return a list containing the periods of self between 1 and $n-1$, where n is the length of self.

INPUT:

- divide_length – boolean (default: False). When set to True, then only periods that divide the length of self are considered.

OUTPUT:

a list of positive integers

EXAMPLES:

```
sage: w = Word('ababab')
sage: w.periods()
[2, 4]
sage: w.periods(divide_length=True)
[2]
sage: w = Word('ababa')
sage: w.periods()
[2, 4]
sage: w.periods(divide_length=True)
[]
```

phi()

Apply the phi function to `self` and return the result. This is the word obtained by taking the first letter of the words obtained by iterating delta on `self`.

OUTPUT:

a word – the result of the phi function

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([2,2,1,1,2,1,2,2,1,2,2,1,1,2]).phi()
word: 222222
sage: W([2,1,2,2,1,2,2,1,2,1]).phi()
word: 212113
sage: W().phi()
word:
sage: Word([2,1,2,2,1,2,2,1,2,1]).phi()
word: 212113
sage: Word([2,3,1,1,2,1,2,3,1,2,2,3,1,2]).phi()
word: 21215
sage: Word("aabbabaabaabba").phi()
word: a22222
sage: w = Word([2,3,1,1,2,1,2,3,1,2,2,3,1,2])
```

See [BL2003] and [BDLV2006].

phi_inv(*W=None*)

Apply the inverse of the phi function to `self`.

INPUT:

- `self` – a word over the integers
- `W` – a parent object of words defined over integers

OUTPUT:

a word – the inverse of the phi function

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([2, 2, 2, 2, 1, 2]).phi_inv()
word: 22112122
sage: W([2, 2, 2]).phi_inv(Words([2, 3]))
word: 2233
```

prefix_function_table()

Return a vector containing the length of the proper prefix-suffixes for all the non-empty prefixes of `self`.

EXAMPLES:

```
sage: Word('121321').prefix_function_table()
[0, 0, 1, 0, 0, 1]
sage: Word('1241245').prefix_function_table()
[0, 0, 0, 1, 2, 3, 0]
sage: Word().prefix_function_table()
[]
```

primitive()

Return the primitive of `self`.

EXAMPLES:

```
sage: Word('12312').primitive()
word: 12312
sage: Word('121212').primitive()
word: 12
```

primitive_length()

Return the length of the primitive of `self`.

EXAMPLES:

```
sage: Word('1231').primitive_length()
4
sage: Word('121212').primitive_length()
2
```

quasiperiods()

Return the quasiperiods of `self` as a list ordered from shortest to longest.

Let w be a finite or infinite word. A *quasiperiod* of w is a proper factor u of w such that the occurrences of u in w entirely cover w, i.e., every position of w falls within some occurrence of u in w. See for instance [AE1993], [Mar2004], and [GLR2008].

EXAMPLES:

```
sage: Word('abaababaabaababababaaba').quasiperiods()
[word: aba, word: abaaba, word: abaababaaba]
sage: Word('abaaba').quasiperiods()
[word: aba]
sage: Word('abacaba').quasiperiods()
[]
```

rauzy_graph(*n*)

Return the Rauzy graph of the factors of length `n` of `self`.

The vertices are the factors of length n and there is an edge from u to v if $ua = bv$ is a factor of length $n+1$ for some letters a and b.

INPUT:

- `n` – integer

EXAMPLES:

```
sage: w = Word(range(10)); w
word: 0123456789
sage: g = w.rauzy_graph(3); g                                                 #␣
↪needs sage.graphs
Looped digraph on 8 vertices
sage: WordOptions(identifier='')
sage: g.vertices(sort=True)                                                   #␣
↪needs sage.graphs
[012, 123, 234, 345, 456, 567, 678, 789]
sage: g.edges(sort=True)                                                      #␣
↪needs sage.graphs
[(012, 123, 3),
 (123, 234, 4),
 (234, 345, 5),
 (345, 456, 6),
 (456, 567, 7),
 (567, 678, 8),
 (678, 789, 9)]
sage: WordOptions(identifier='word: ')
```

```
sage: f = words.FibonacciWord()[:100]
sage: f.rauzy_graph(8)                                                        #␣
↪needs sage.graphs
Looped digraph on 9 vertices
```

```
sage: w = Word('1111111')
sage: g = w.rauzy_graph(3)                                                    #␣
↪needs sage.graphs
sage: g.edges(sort=True)                                                      #␣
↪needs sage.graphs
[(word: 111, word: 111, word: 1)]
```

```
sage: w = Word('111')
sage: for i in range(5): w.rauzy_graph(i)                                     #␣
↪needs sage.graphs
Looped multi-digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 0 vertices
```

Multi-edges are allowed for the empty word:

```
sage: W = Words('abcde')
sage: w = W('abc')
sage: w.rauzy_graph(0)                                                        #␣
↪needs sage.graphs
Looped multi-digraph on 1 vertex
sage: _.edges(sort=True)                                                      #␣
↪needs sage.graphs
[(word: , word: , word: a),
 (word: , word: , word: b),
 (word: , word: , word: c)]
```

reduced_rauzy_graph(*n*)

Return the reduced Rauzy graph of order `n` of `self`.

INPUT:

- `n` – a non-negative integer. Every vertex of a reduced Rauzy graph of order `n` is a factor of length `n` of `self`.

OUTPUT:

a looped multi-digraph

DEFINITION:

For infinite periodic words (resp. for finite words of type $u^i u[0:j]$), the reduced Rauzy graph of order n (resp. for n smaller or equal to $(i-1)|u|+j$) is the directed graph whose unique vertex is the prefix p of length n of `self` and which has an only edge which is a loop on p labelled by $w[n+1:|w|]p$ where w is the unique return word to p.

In other cases, it is the directed graph defined as followed. Let G_n be the Rauzy graph of order n of self. The vertices are the vertices of G_n that are either special or not prolongable to the right or to the left. For each couple (u, v) of such vertices and each directed path in G_n from u to v that contains no other vertices that are special, there is an edge from u to v in the reduced Rauzy graph of order n whose label is the label of the path in G_n.

Note: In the case of infinite recurrent non-periodic words, this definition corresponds to the following one that can be found in [BDLGZ2009] and [BPS2008] where a simple path is a path that begins with a special factor, ends with a special factor and contains no other vertices that are special:

The reduced Rauzy graph of factors of length n is obtained from G_n by replacing each simple path $P = v_1 v_2 ... v_\ell$ with an edge $v_1 v_\ell$ whose label is the concatenation of the labels of the edges of P.

EXAMPLES:

```
sage: w = Word(range(10)); w
word: 0123456789
sage: g = w.reduced_rauzy_graph(3); g                                          #␣
↪needs sage.graphs
Looped multi-digraph on 2 vertices
sage: g.vertices(sort=True)                                                    #␣
↪needs sage.graphs
[word: 012, word: 789]
sage: g.edges(sort=True)                                                       #␣
↪needs sage.graphs
[(word: 012, word: 789, word: 3456789)]
```

For the Fibonacci word:

```
sage: f = words.FibonacciWord()[:100]
sage: g = f.reduced_rauzy_graph(8);g                                           #␣
↪needs sage.graphs
Looped multi-digraph on 2 vertices
sage: g.vertices(sort=True)                                                    #␣
↪needs sage.graphs
[word: 01001010, word: 01010010]
sage: g.edges(sort=True)                                                       #␣
↪needs sage.graphs
[(word: 01001010, word: 01010010, word: 010),
 (word: 01010010, word: 01001010, word: 01010),
 (word: 01010010, word: 01001010, word: 10)]
```

For periodic words:

```
sage: from itertools import cycle
sage: w = Word(cycle('abcd'))[:100]
sage: g = w.reduced_rauzy_graph(3)                                          #␣
↪needs sage.graphs
sage: g.edges(sort=True)                                                    #␣
↪needs sage.graphs
[(word: abc, word: abc, word: dabc)]
```

```
sage: w = Word('111')
sage: for i in range(5): w.reduced_rauzy_graph(i)                           #␣
↪needs sage.graphs
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped multi-digraph on 1 vertex
Looped multi-digraph on 0 vertices
```

For ultimately periodic words:

```
sage: sigma = WordMorphism('a->abcd,b->cd,c->cd,d->cd')
sage: w = sigma.fixed_point('a')[:100]; w                                   #␣
↪needs sage.modules
word: abcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcd...
sage: g = w.reduced_rauzy_graph(5)                                          #␣
↪needs sage.graphs
sage: g.vertices(sort=True)                                                 #␣
↪needs sage.graphs
[word: abcdc, word: cdcdc]
sage: g.edges(sort=True)                                                    #␣
↪needs sage.graphs
[(word: abcdc, word: cdcdc, word: dc), (word: cdcdc, word: cdcdc, word: dc)]
```

AUTHOR:

Julien Leroy (March 2010): initial version

return_words (*fact*)

Return the set of return words of `fact` in `self`.

This is the set of all factors starting by the given factor and ending just before the next occurrence of this factor. See [Dur1998] and [HZ1999].

INPUT:

- `fact` – a non-empty finite word

OUTPUT:

a Python set of finite words

EXAMPLES:

```
sage: Word('21331233213231').return_words(Word('2'))
{word: 213, word: 21331, word: 233}
sage: Word().return_words(Word('213'))
set()
sage: Word('121212').return_words(Word('1212'))
{word: 12}
```

```
sage: TM = words.ThueMorseWord()[:1000]
sage: sorted(TM.return_words(Word([0])))
[word: 0, word: 01, word: 011]
```

return_words_derivate (*fact*)

Return the word generated by mapping a letter to each occurrence of the return words for the given factor dropping any dangling prefix and suffix. See for instance [Dur1998].

EXAMPLES:

```
sage: Word('12131221312313122').return_words_derivate(Word('1'))
word: 123242
```

rev_lex_less (*other*)

Return `True` if the word `self` is reverse lexicographically less than `other`.

EXAMPLES:

```
sage: Word([1,2,4]).rev_lex_less(Word([1,3,2]))
True
sage: Word([3,2,1]).rev_lex_less(Word([1,2,3]))
False
```

reversal ()

Return the reversal of `self`.

EXAMPLES:

```
sage: Word('124563').reversal()
word: 365421
```

rfind (*sub*, *start=0*, *end=None*)

Return the index of the last occurrence of `sub` in `self`, such that `sub` is contained within `self[start:end]`. Return `-1` on failure.

INPUT:

- `sub` – string, list, tuple or word to search for.
- `start` – non-negative integer (default: `0`) specifying the position at which the search must stop.
- `end` – non-negative integer (default: `None`) specifying the position from which to start the search. If `None`, then the search is performed up to the end of the string.

OUTPUT:

a non-negative integer or `-1`

EXAMPLES:

```
sage: w = Word([0,1,0,0,1])
sage: w.rfind(Word([0,1]))
3
```

The `sub` parameter can also be a list or a tuple:

```
sage: w.rfind([0,1])
3
sage: w.rfind((0,1))
3
```

Examples using the argument `start` and `end`:

```
sage: w.rfind(Word([0,1]), end=4)
0
sage: w.rfind(Word([0,1]), end=5)
3
sage: w.rfind(Word([0,0]), start=2, end=5)
2
sage: w.rfind(Word([0,0]), start=3, end=5)
-1
```

Instances of `Word_str` handle string inputs as well:

```
sage: w = Word('abac')
sage: w.rfind('a')
2
sage: w.rfind(Word('a'))
2
sage: w.rfind([0,1])
-1
```

right_special_factors (*n=None*)

Return the right special factors (of length `n`).

A factor u of a word w is *right special* if there are two distinct letters a and b such that ua and ub are factors of w.

INPUT:

- `n` – integer (default: `None`). If `None`, it returns all right special factors.

OUTPUT:

a list of words

EXAMPLES:

```
sage: w = words.ThueMorseWord()[:30]
sage: for i in range(5):
....:     print("{} {}".format(i, sorted(w.right_special_factors(i))))
0 [word: ]
1 [word: 0, word: 1]
2 [word: 01, word: 10]
3 [word: 001, word: 010, word: 101, word: 110]
4 [word: 0110, word: 1001]
```

right_special_factors_iterator (*n=None*)

Return an iterator over the right special factors (of length `n`).

A factor u of a word w is *right special* if there are two distinct letters a and b such that ua and ub are factors of w.

INPUT:

- `n` – integer (default: `None`). If `None`, it returns an iterator over all right special factors.

EXAMPLES:

```
sage: alpha, beta, x = 0.61, 0.54, 0.3
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: sorted(w.right_special_factors_iterator(3))
```

(continues on next page)

(continued from previous page)

```
[word: 010, word: 101]
sage: sorted(w.right_special_factors_iterator(4))
[word: 0101, word: 1010]
sage: sorted(w.right_special_factors_iterator(5))
[word: 00101, word: 11010]
```

robinson_schensted()

Return the semistandard tableau and standard tableau pair obtained by running the Robinson-Schensted algorithm on `self`.

This can also be done by running *RSK()* on `self`.

EXAMPLES:

```
sage: Word([1,1,3,1,2,3,1]).robinson_schensted()
[[[1, 1, 1, 1, 3], [2], [3]], [[1, 2, 3, 5, 6], [4], [7]]]
```

schuetzenberger_involution(*n=None*)

Return the Schützenberger involution of the word `self`, which is obtained by reverting the word and then complementing all letters within the underlying ordered alphabet. If `n` is specified, the underlying alphabet is assumed to be $[1, 2, \ldots, n]$. If no alphabet is specified, n is the maximal letter appearing in `self`.

INPUT:

- `self` – a word
- `n` – an integer specifying the maximal letter in the alphabet (optional)

OUTPUT:

a word, the Schützenberger involution of `self`

EXAMPLES:

```
sage: w = Word([9,7,4,1,6,2,3])
sage: v = w.schuetzenberger_involution(); v
word: 7849631
sage: v.parent()
Finite words over Set of Python objects of class 'object'

sage: w = Word([1,2,3],alphabet=[1,2,3,4,5])
sage: v = w.schuetzenberger_involution();v
word: 345
sage: v.parent()
Finite words over {1, 2, 3, 4, 5}

sage: w = Word([1,2,3])
sage: v = w.schuetzenberger_involution(n=5);v
word: 345
sage: v.parent()
Finite words over Set of Python objects of class 'object'

sage: w = Word([11,32,69,2,53,1,2,3,18,41])
sage: w.schuetzenberger_involution()
word: 29,52,67,68,69,17,68,1,38,59

sage: w = Word([],alphabet=[1,2,3,4,5])
sage: w.schuetzenberger_involution()
word:
```

(continues on next page)

(continued from previous page)

```
sage: w = Word([])
sage: w.schuetzenberger_involution()
word:
```

shifted_shuffle(*other*, *shift=None*)

Return the combinatorial class representing the shifted shuffle product between words `self` and `other`. This is the same as the shuffle product of `self` with the word obtained from `other` by incrementing its values (i.e. its letters) by the given `shift`.

INPUT:

- `other` – finite word over the integers
- `shift` – integer or `None` (default: `None`) added to each letter of `other`. When `shift` is `None`, it is replaced by `self.length()`

OUTPUT:

combinatorial class of shifted shuffle products of `self` and `other`

EXAMPLES:

```
sage: w = Word([0,1,1])
sage: sp = w.shifted_shuffle(w); sp
Shuffle product of word: 011 and word: 344
sage: sp = w.shifted_shuffle(w, 2); sp
Shuffle product of word: 011 and word: 233
sage: sp.cardinality()
20
sage: WordOptions(identifier='')
sage: sp.list()
[011233, 012133, 012313, 012331, 021133, 021313, 021331, 023113, 023131,␣
↪023311, 201133, 201313, 201331, 203113, 203131, 203311, 230113, 230131,␣
↪230311, 233011]
sage: WordOptions(identifier='word: ')
sage: y = Word('aba')
sage: y.shifted_shuffle(w,2)
Traceback (most recent call last):
...
ValueError: for shifted shuffle, words must only contain integers as letters
```

shuffle(*other*, *overlap=0*)

Return the combinatorial class representing the shuffle product between words `self` and `other`. This consists of all words of length `self.length()+other.length()` that have both `self` and `other` as subwords.

If `overlap` is non-zero, then the combinatorial class representing the shuffle product with overlaps is returned. The calculation of the shift in each overlap is done relative to the order of the alphabet. For example, a shifted by a is b in the alphabet $[a, b, c]$ and 0 shifted by 1 in $[0, 1, 2, 3]$ is 2.

INPUT:

- `other` – finite word
- `overlap` – (default: `0`) integer or `True`

OUTPUT:

combinatorial class of shuffle product of `self` and `other`

EXAMPLES:

```
sage: ab = Word("ab")
sage: cd = Word("cd")
sage: sp = ab.shuffle(cd); sp
Shuffle product of word: ab and word: cd
sage: sp.cardinality()
6
sage: sp.list()
[word: abcd, word: acbd, word: acdb, word: cabd, word: cadb, word: cdab]
sage: w = Word([0,1])
sage: u = Word([2,3])
sage: w.shuffle(w)
Shuffle product of word: 01 and word: 01
sage: u.shuffle(u)
Shuffle product of word: 23 and word: 23
sage: w.shuffle(u)
Shuffle product of word: 01 and word: 23
sage: sp2 = w.shuffle(u,2); sp2
Overlapping shuffle product of word: 01 and word: 23 with 2 overlaps
sage: list(sp2)
[word: 24]
```

squares()

Returns a set of all distinct squares of `self`.

EXAMPLES:

```
sage: sorted(Word('cacao').squares())
[word: , word: caca]
sage: sorted(Word('1111').squares())
[word: , word: 11, word: 1111]
sage: w = Word('00110011010')
sage: sorted(w.squares())
[word: , word: 00, word: 00110011, word: 01100110, word: 1010, word: 11]
```

standard_factorization()

Return the standard factorization of `self`.

The *standard factorization* of a word w of length greater than 1 is the factorization $w = uv$ where v is the longest proper suffix of w that is a Lyndon word.

Note that if w is a Lyndon word of length greater than 1 with standard factorization $w = uv$, then u and v are also Lyndon words and $u < v$.

See for instance [CFL1958], [Duv1983] and [Lot2002].

INPUT:

- `self` – finite word of length greater than 1

OUTPUT:

2-tuple (u, v)

EXAMPLES:

```
sage: Words('01')('0010110011').standard_factorization()
(word: 001011, word: 0011)
sage: Words('123')('1223312').standard_factorization()
```

(continues on next page)

(continued from previous page)

```
(word: 12233, word: 12)
sage: Word([3,2,1]).standard_factorization()
(word: 32, word: 1)
```

```
sage: w = Word('0010110011',alphabet='01')
sage: w.standard_factorization()
(word: 001011, word: 0011)
sage: w = Word('0010110011',alphabet='10')
sage: w.standard_factorization()
(word: 001011001, word: 1)
sage: w = Word('1223312',alphabet='123')
sage: w.standard_factorization()
(word: 12233, word: 12)
```

standard_permutation()

Return the standard permutation of the word `self` on the ordered alphabet. It is defined as the permutation with exactly the same inversions as `self`. Equivalently, it is the permutation of minimal length whose inverse sorts `self`.

EXAMPLES:

```
sage: w = Word([1,2,3,2,2,1]); w
word: 123221
sage: p = w.standard_permutation(); p
[1, 3, 6, 4, 5, 2]
sage: v = Word(p.inverse().action(w)); v
word: 112223
sage: [q for q in Permutations(w.length())
....:       if q.length() <= p.length() and
....:       q.inverse().action(w) == list(v)]
[[1, 3, 6, 4, 5, 2]]
```

```
sage: w = Words([1,2,3])([1,2,3,2,2,1,2,1]); w
word: 12322121
sage: p = w.standard_permutation(); p
[1, 4, 8, 5, 6, 2, 7, 3]
sage: Word(p.inverse().action(w))
word: 11122223
```

```
sage: w = Words([3,2,1])([1,2,3,2,2,1,2,1]); w
word: 12322121
sage: p = w.standard_permutation(); p
[6, 2, 1, 3, 4, 7, 5, 8]
sage: Word(p.inverse().action(w))
word: 32222111
```

```
sage: w = Words('ab')('abbaba'); w
word: abbaba
sage: p = w.standard_permutation(); p
[1, 4, 5, 2, 6, 3]
sage: Word(p.inverse().action(w))
word: aaabbb
```

```
sage: w = Words('ba')('abbaba'); w
word: abbaba
```

(continues on next page)

(continued from previous page)

```
sage: p = w.standard_permutation(); p
[4, 1, 2, 5, 3, 6]
sage: Word(p.inverse().action(w))
word: bbbaaa
```

sturmian_desubstitute_as_possible()

Sturmian-desubstitute the word `self` as much as possible.

The finite word `self` must be defined on a two-letter alphabet or use at most two letters.

It can be Sturmian desubstituted if one letter appears isolated: the Sturmian desubstitution consists in removing one letter per run of the non-isolated letter. The accelerated Sturmian desubstitution consists in removing a run equal to the length of the shortest inner run from any run of the non-isolated letter (including possible leading and trailing runs even if they have shorter length). The (accelerated) Sturmian desubstitution is done as much as possible. A word is a factor of a Sturmian word if, and only if, the result is the empty word.

OUTPUT:

a finite word defined on a two-letter alphabet

EXAMPLES:

```
sage: u = Word('10111101101110111',alphabet='01') ; u
word: 10111101101110111
sage: v = u.sturmian_desubstitute_as_possible() ; v
word: 01100101
sage: v == v.sturmian_desubstitute_as_possible()
True

sage: Word('azaazaaazaaaazaazaaaz', alphabet='az').sturmian_desubstitute_as_
↪possible()
word:
```

AUTHOR:

- Thierry Monteil

subword_complementaries(*other*)

Return the possible complementaries `other` minus `self` if `self` is a subword of `other` (empty list otherwise). The complementary is made of all the letters that are in `other` once we removed the letters of `self`. There can be more than one.

To check whether `self` is a subword of `other` (without knowing its complementaries), use `self.is_subword_of(other)`, and to count the number of occurrences of `self` in `other`, use `other.number_of_subword_occurrences(self)`.

INPUT:

- `other` – finite word

OUTPUT:

- list of all the complementary subwords of `self` in `other`.

EXAMPLES:

```
sage: Word('tamtam').subword_complementaries(Word('ta'))
[]

sage: Word('mta').subword_complementaries(Word('tamtam'))
```

(continues on next page)

(continued from previous page)

```
[word: tam]

sage: Word('ta').subword_complementaries(Word('tamtam'))
[word: mtam, word: amtm, word: tamm]

sage: Word('a').subword_complementaries(Word('a'))
[word: ]
```

suffix_tree()

Alias for `implicit_suffix_tree()`.

EXAMPLES:

```
sage: Word('abbabaab').suffix_tree()
Implicit Suffix Tree of the word: abbabaab
```

suffix_trie()

Return the suffix trie of `self`.

The *suffix trie* of a finite word w is a data structure representing the factors of w. It is a tree whose edges are labelled with letters of w, and whose leafs correspond to suffixes of w.

Type `sage.combinat.words.suffix_trees.SuffixTrie?` for more information.

EXAMPLES:

```
sage: w = Word("cacao")
sage: w.suffix_trie()
Suffix Trie of the word: cacao
```

```
sage: w = Word([0,1,0,1,1])
sage: w.suffix_trie()
Suffix Trie of the word: 01011
```

swap(*i*, *j=None*)

Return the word w with entries at positions `i` and `j` swapped. By default, `j = i+1`.

EXAMPLES:

```
sage: Word([1,2,3]).swap(0,2)
word: 321
sage: Word([1,2,3]).swap(1)
word: 132
sage: Word("abba").swap(1,-1)
word: aabb
```

swap_decrease(*i*)

Return the word with positions `i` and `i+1` exchanged if `self[i] < self[i+1]`. Otherwise, it returns `self`.

EXAMPLES:

```
sage: w = Word([1,3,2])
sage: w.swap_decrease(0)
word: 312
sage: w.swap_decrease(1)
word: 132
```

(continues on next page)

(continued from previous page)

```
sage: w.swap_decrease(1) is w
True
sage: Words("ab")("abba").swap_decrease(0)
word: baba
sage: Words("ba")("abba").swap_decrease(0)
word: abba
```

swap_increase(*i*)

Return the word with positions `i` and `i+1` exchanged if `self[i] > self[i+1]`. Otherwise, it returns `self`.

EXAMPLES:

```
sage: w = Word([1,3,2])
sage: w.swap_increase(1)
word: 123
sage: w.swap_increase(0)
word: 132
sage: w.swap_increase(0) is w
True
sage: Words("ab")("abba").swap_increase(0)
word: abba
sage: Words("ba")("abba").swap_increase(0)
word: baba
```

to_integer_list()

Return a list of integers from `[0,1,...,self.length()-1]` in the same relative order as the letters in `self` in the parent.

EXAMPLES:

```
sage: from itertools import count
sage: w = Word('abbabaab')
sage: w.to_integer_list()
[0, 1, 1, 0, 1, 0, 0, 1]
sage: w = Word(iter("cacao"), length="finite")
sage: w.to_integer_list()
[1, 0, 1, 0, 2]
sage: w = Words([3,2,1])([2,3,3,1])
sage: w.to_integer_list()
[1, 0, 0, 2]
```

to_integer_word()

Return a word over the alphabet `[0,1,...,self.length()-1]` whose letters are in the same relative order as the letters of `self` in the parent.

EXAMPLES:

```
sage: from itertools import count
sage: w = Word('abbabaab')
sage: w.to_integer_word()
word: 01101001
sage: w = Word(iter("cacao"), length="finite")
sage: w.to_integer_word()
word: 10102
```

(continues on next page)

(continued from previous page)

```
sage: w = Words([3,2,1])([2,3,3,1])
sage: w.to_integer_word()
word: 1002
```

to_monoid_element()

Return `self` as an element of the free monoid with the same alphabet as `self`.

EXAMPLES:

```
sage: w = Word('aabb')
sage: w.to_monoid_element()
a^2*b^2
sage: W = Words('abc')
sage: w = W(w)
sage: w.to_monoid_element()
a^2*b^2
```

to_ordered_set_partition()

Return the ordered set partition correspond to `self`.

If w is a finite word of length n, then the corresponding ordered set partition is an ordered set partition $(P_1, P_2, \ldots, P_k)$ of $\{1, 2, \ldots, n\}$, where each block P_i is the set of positions at which the i-th smallest letter occurring in w occurs in w.

EXAMPLES:

```
sage: w = Word('abbabaab')
sage: w.to_ordered_set_partition()
[{1, 4, 6, 7}, {2, 3, 5, 8}]
sage: Word([-10, 3, -10, 2]).to_ordered_set_partition()
[{1, 3}, {4}, {2}]
sage: Word([]).to_ordered_set_partition()
[]
sage: Word('aaaaa').to_ordered_set_partition()
[{1, 2, 3, 4, 5}]
```

topological_entropy(*n*)

Return the topological entropy for the factors of length `n`.

The topological entropy of a sequence u is defined as the exponential growth rate of the complexity of u as the length increases: $H_{top}(u) = \lim_{n\to\infty} \frac{\log_d(p_u(n))}{n}$ where d denotes the cardinality of the alphabet and $p_u(n)$ is the complexity function, i.e. the number of factors of length n in the sequence u [Fog2002].

INPUT:

- `self` – a word defined over a finite alphabet
- `n` – positive integer

OUTPUT:

real number (a symbolic expression)

EXAMPLES:

```
sage: W = Words([0, 1])
sage: w = W([0, 1, 0, 0, 0, 1, 1, 0, 0, 1, 0, 1])
sage: t = w.topological_entropy(3); t                                    #␣
↪needs sage.symbolic
```

(continues on next page)

(continued from previous page)

```
1/3*log(7)/log(2)
sage: n(t)                                                                  #␣
↪needs sage.symbolic
0.935784974019201
```

```
sage: w = words.ThueMorseWord()[:100]
sage: topo = w.topological_entropy
sage: for i in range(0, 41, 5):                                             #␣
↪needs sage.symbolic
....:     print("{} {}".format(i, n(topo(i), digits=5)))
0 1.0000
5 0.71699
10 0.48074
15 0.36396
20 0.28774
25 0.23628
30 0.20075
35 0.17270
40 0.14827
```

If no alphabet is specified, an error is raised:

```
sage: w = Word(range(20))
sage: w.topological_entropy(3)
Traceback (most recent call last):
...
TypeError: The word must be defined over a finite alphabet
```

The following is ok:

```
sage: W = Words(range(20))
sage: w = W(range(20))
sage: w.topological_entropy(3)                                              #␣
↪needs sage.symbolic
1/3*log(18)/log(20)
```

sage.combinat.words.finite_word.**evaluation_dict**(*w*)

Return a dictionary keyed by the letters occurring in `w` with values the number of occurrences of the letter.

INPUT:

- `w` – a word

sage.combinat.words.finite_word.**word_to_ordered_set_partition**(*w*)

Return the ordered set partition corresponding to a finite word w.

If w is a finite word of length n, then the corresponding ordered set partition is an ordered set partition $(P_1, P_2, \ldots, P_k)$ of $\{1, 2, \ldots, n\}$, where each block P_i is the set of positions at which the i-th smallest letter occurring in w occurs in w. (Positions are 1-based.)

This is the same functionality that *to_ordered_set_partition()* provides, but without the wrapping: The input w can be given as a list or tuple, not necessarily as a word; and the output is returned as a list of lists (which are the blocks of the ordered set partition in increasing order), not as an ordered set partition.

EXAMPLES:

```
sage: from sage.combinat.words.finite_word import word_to_ordered_set_partition
sage: word_to_ordered_set_partition([3, 6, 3, 1])
[[4], [1, 3], [2]]
sage: word_to_ordered_set_partition((1, 3, 3, 7))
[[1], [2, 3], [4]]
sage: word_to_ordered_set_partition("noob")
[[4], [1], [2, 3]]
sage: word_to_ordered_set_partition(Word("hell"))
[[2], [1], [3, 4]]
sage: word_to_ordered_set_partition([1])
[[1]]
sage: word_to_ordered_set_partition([])
[]
```

5.1.359 Infinite word

AUTHORS:

- Sebastien Labbe
- Franco Saliola

EXAMPLES:

Creation of an infinite word

Periodic infinite words:

```
sage: v = Word([0, 4, 8, 8, 3])
sage: vv = v^Infinity
sage: vv
word: 048830488304883048830488304883048830488304883...
```

Infinite words from a function $f : \mathbb{N} \to A$ over an alphabet A:

```
sage: Word(lambda n: n%3)
word: 012012012012012012012012012012012012012012012...
```

```
sage: def t(n):
....:     return add(Integer(n).digits(base=2)) % 2
sage: Word(t, alphabet = [0, 1])
word: 011010011001011010010110011010011001011010010...
```

or as a one-liner:

```
sage: Word(lambda n : add(Integer(n).digits(base=2)) % 2, alphabet = [0, 1])
word: 011010011001011010010110011010011001011010010...
```

Infinite words from iterators:

```
sage: from itertools import count,repeat
sage: Word( repeat(4) )
word: 444444444444444444444444444444444444444444...
sage: Word( count() )
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,28,29,
↪30,31,32,33,34,35,36,37,38,39,...
```

Infinite words from morphism

For example, let $A = \{a, b\}$ and $\mu : A^* \to A^*$ be the morphism defined by $a \mapsto ab, b \mapsto ba$:

```
sage: mu = WordMorphism('a->ab,b->ba'); mu
WordMorphism: a->ab, b->ba
sage: mu.fixed_point('a')
word: abbabaabbaababbabaababbaabbabaabbaababba...
```

Infinite words in a specific combinatorial class:

```
sage: W = InfiniteWords("ab"); W
Infinite words over {'a', 'b'}
sage: f = lambda n : 'a' if n % 2 == 1 else 'b'
sage: W(f)
word: bababababababababababababababababababa...
```

class sage.combinat.words.infinite_word.**InfiniteWord_class**

Bases: *Word_class*

length()

Returns the length of self.

EXAMPLES:

```
sage: f = lambda n : n % 6
sage: w = Word(f); w
word: 012345012345012345012345012345012345012345...
sage: w.length()
+Infinity
```

5.1.360 Lyndon words

sage.combinat.words.lyndon_word.**LyndonWord**(*data*, *check=True*)

Construction of a Lyndon word.

INPUT:

- `data` – list
- `check` – bool (default: `True`) if `True`, check that the input data represents a Lyndon word.

OUTPUT:

A Lyndon word.

EXAMPLES:

```
sage: LyndonWord([1,2,2])
word: 122
sage: LyndonWord([1,2,3])
word: 123
sage: LyndonWord([2,1,2,3])
Traceback (most recent call last):
...
ValueError: not a Lyndon word
```

If `check` is `False`, then no verification is done:

```
sage: LyndonWord([2,1,2,3], check=False)
word: 2123
```

sage.combinat.words.lyndon_word.**LyndonWords**(*e=None*, *k=None*)

Return the combinatorial class of Lyndon words.

A Lyndon word w is a word that is lexicographically less than all of its rotations. Equivalently, whenever w is split into two non-empty substrings, w is lexicographically less than the right substring.

See Wikipedia article Lyndon_word

INPUT:

- no input at all

or

- `e` – integer, size of alphabet
- `k` – integer, length of the words

or

- `e` – a composition

OUTPUT:

A combinatorial class of Lyndon words.

EXAMPLES:

```
sage: LyndonWords()
Lyndon words
```

If e is an integer, then e specifies the length of the alphabet; k must also be specified in this case:

```
sage: LW = LyndonWords(3, 4); LW
Lyndon words from an alphabet of size 3 of length 4
sage: LW.first()
word: 1112
sage: LW.last()
word: 2333
sage: LW.random_element()  # random                                    #␣
↪needs sage.libs.pari
word: 1232
sage: LW.cardinality()                                                 #␣
↪needs sage.libs.pari
18
```

If e is a (weak) composition, then it returns the class of Lyndon words that have evaluation e:

```
sage: LyndonWords([2, 0, 1]).list()
[word: 113]
sage: LyndonWords([2, 0, 1, 0, 1]).list()
[word: 1135, word: 1153, word: 1315]
sage: LyndonWords([2, 1, 1]).list()
[word: 1123, word: 1132, word: 1213]
```

class sage.combinat.words.lyndon_word.**LyndonWords_class**(*alphabet=None*)

Bases: `UniqueRepresentation`, `Parent`

The set of all Lyndon words.

class sage.combinat.words.lyndon_word.**LyndonWords_evaluation**(*e*)

Bases: UniqueRepresentation, Parent

The set of Lyndon words on a fixed multiset of letters.

EXAMPLES:

```
sage: L = LyndonWords([1,2,1])
sage: L
Lyndon words with evaluation [1, 2, 1]
sage: L.list()
[word: 1223, word: 1232, word: 1322]
```

cardinality()

Return the number of Lyndon words with the evaluation e.

EXAMPLES:

```
sage: LyndonWords([]).cardinality()
0
sage: LyndonWords([2,2]).cardinality()                                    #␣
↪needs sage.libs.pari
1
sage: LyndonWords([2,3,2]).cardinality()                                  #␣
↪needs sage.libs.pari
30
```

Check to make sure that the count matches up with the number of Lyndon words generated:

```
sage: comps = [[],[2,2],[3,2,7],[4,2]] + Compositions(4).list()
sage: lws = [LyndonWords(comp) for comp in comps]
sage: all(lw.cardinality() == len(lw.list()) for lw in lws)               #␣
↪needs sage.libs.pari
True
```

class sage.combinat.words.lyndon_word.**LyndonWords_nk**(*n*, *k*)

Bases: UniqueRepresentation, Parent

Lyndon words of fixed length k over the alphabet $\{1, 2, \ldots, n\}$.

INPUT:

- n – the size of the alphabet
- k – the length of the words

EXAMPLES:

```
sage: L = LyndonWords(3, 4)
sage: L.list()
[word: 1112,
 word: 1113,
 word: 1122,
 word: 1123,
 ...
 word: 1333,
 word: 2223,
 word: 2233,
 word: 2333]
```

cardinality()

sage.combinat.words.lyndon_word.**StandardBracketedLyndonWords**(*n*, *k*)

Return the combinatorial class of standard bracketed Lyndon words from [1, …, n] of length k.

These are in one to one correspondence with the Lyndon words and form a basis for the subspace of degree k of the free Lie algebra of rank n.

EXAMPLES:

```
sage: SBLW33 = StandardBracketedLyndonWords(3,3); SBLW33
Standard bracketed Lyndon words from an alphabet of size 3 of length 3
sage: SBLW33.first()
[1, [1, 2]]
sage: SBLW33.last()
[[2, 3], 3]
sage: SBLW33.cardinality()
8
sage: SBLW33.random_element() in SBLW33
True
```

class sage.combinat.words.lyndon_word.**StandardBracketedLyndonWords_nk**(*n*, *k*)

Bases: UniqueRepresentation, Parent

cardinality()

EXAMPLES:

```
sage: StandardBracketedLyndonWords(3, 3).cardinality()
8
sage: StandardBracketedLyndonWords(3, 4).cardinality()
18
```

sage.combinat.words.lyndon_word.**standard_bracketing**(*lw*)

Return the standard bracketing of a Lyndon word lw.

EXAMPLES:

```
sage: import sage.combinat.words.lyndon_word as lyndon_word
sage: [lyndon_word.standard_bracketing(u) for u in LyndonWords(3,3)]
[[1, [1, 2]],
 [1, [1, 3]],
 [[1, 2], 2],
 [1, [2, 3]],
 [[1, 3], 2],
 [[1, 3], 3],
 [2, [2, 3]],
 [[2, 3], 3]]
```

sage.combinat.words.lyndon_word.**standard_unbracketing**(*sblw*)

Return flattened sblw if it is a standard bracketing of a Lyndon word, otherwise raise an error.

EXAMPLES:

```
sage: from sage.combinat.words.lyndon_word import standard_unbracketing
sage: standard_unbracketing([1, [2, 3]])
word: 123
sage: standard_unbracketing([[1, 2], 3])
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: not a standard bracketing of a Lyndon word
```

5.1.361 Word morphisms/substitutions

This module implements morphisms over finite and infinite words.

AUTHORS:

- Sébastien Labbé (2007-06-01): initial version
- Sébastien Labbé (2008-07-01): merged into sage-words
- Sébastien Labbé (2008-12-17): merged into sage
- Sébastien Labbé (2009-02-03): words next generation
- Sébastien Labbé (2009-11-20): allowing the choice of the datatype of the image. Doc improvements.
- Stepan Starosta (2012-11-09): growing letters

EXAMPLES:

Creation of a morphism from a dictionary or a string:

```
sage: n = WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]})
```

```
sage: m = WordMorphism('x->xyxsxss,s->xyss,y->ys')
```

```
sage: n
WordMorphism: 0->0221, 1->02, 2->221
sage: m
WordMorphism: s->xyss, x->xyxsxss, y->ys
```

The codomain may be specified:

```
sage: WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]}, codomain=Words([0,1,2,3,4]))
WordMorphism: 0->0221, 1->02, 2->221
```

Power of a morphism:

```
sage: n^2
WordMorphism: 0->022122122102, 1->0221221, 2->22122102
```

Image under a morphism:

```
sage: m('y')
word: ys
sage: m('xxxsy')
word: xyxsxssxyxsxssxyxsxssxyssys
```

Iterated image under a morphism:

```
sage: m('y', 3)
word: ysxyssxyxsxssysxyssxyss
```

See more examples in the documentation of the call method (`m.__call__?`).

Infinite fixed point of morphism:

```
sage: fix = m.fixed_point('x')
sage: fix
word: xyxsxssysxyxsxssxyssxyxsxssxyssxyssysxys...
sage: fix.length()
+Infinity
```

Incidence matrix:

```
sage: matrix(m)                                                              #␣
↪needs sage.modules
[2 3 1]
[1 3 0]
[1 1 1]
```

Many other functionalities…:

```
sage: m.is_identity()
False
sage: m.is_endomorphism()
True
```

class sage.combinat.words.morphism.**PeriodicPointIterator**(*m*, *cycle*)

Bases: object

(Lazy) constructor of the periodic points of a word morphism.

This class is mainly used in *WordMorphism.periodic_point* and *WordMorphism.periodic_points*.

EXAMPLES:

```
sage: from sage.combinat.words.morphism import PeriodicPointIterator
sage: s = WordMorphism('a->bacca,b->cba,c->aab')
sage: p = PeriodicPointIterator(s, ['a','b','c'])
sage: p._cache[0]
lazy list ['a', 'a', 'b', ...]
sage: p._cache[1]
lazy list ['b', 'a', 'c', ...]
sage: p._cache[2]
lazy list ['c', 'b', 'a', ...]
```

get_iterator(*i*)

Internal method.

EXAMPLES:

```
sage: from sage.combinat.words.morphism import PeriodicPointIterator
sage: s = WordMorphism('a->bacca,b->cba,c->aab')
sage: p = PeriodicPointIterator(s, ['a','b','c'])
sage: p.get_iterator(0)
<generator object ...get_iterator at ...>
```

class sage.combinat.words.morphism.**WordMorphism**(*data*, *domain=None*, *codomain=None*)

Bases: SageObject

WordMorphism class

INPUT:

- `data` – dict or str or an instance of WordMorphism, the map giving the image of letters
- `domain` – (optional:`None`) set of words over a given alphabet. If `None`, the domain alphabet is computed from `data` and is *sorted*.
- `codomain` – (optional:`None`) set of words over a given alphabet. If `None`, the codomain alphabet is computed from `data` and is *sorted*.

Note: When the domain or the codomain are not explicitly given, it is expected that the letters are comparable because the alphabets of the domain and of the codomain are sorted.

EXAMPLES:

From a dictionary:

```
sage: n = WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]})
sage: n
WordMorphism: 0->0221, 1->02, 2->221
```

From a string with `'->'` as separation:

```
sage: m = WordMorphism('x->xyxsxss,s->xyss,y->ys')
sage: m
WordMorphism: s->xyss, x->xyxsxss, y->ys
sage: m.domain()
Finite words over {'s', 'x', 'y'}
sage: m.codomain()
Finite words over {'s', 'x', 'y'}
```

Specifying the domain and codomain:

```
sage: W = FiniteWords([0,1,2])
sage: d = {0:[0,1], 1:[0,1,0], 2:[0]}
sage: m = WordMorphism(d, domain=W, codomain=W)
sage: m([0]).parent()
Finite words over {0, 1, 2}
```

When the alphabet is non-sortable, the domain and/or codomain must be explicitly given:

```
sage: W = FiniteWords(['a',6])
sage: d = {'a':['a',6,'a'],6:[6,6,6,'a']}
sage: WordMorphism(d, domain=W, codomain=W)
WordMorphism: 6->666a, a->a6a
```

abelian_rotation_subspace()

Return the subspace on which the incidence matrix of `self` acts by roots of unity.

EXAMPLES:

```
sage: # needs sage.modules
sage: WordMorphism('0->1,1->0').abelian_rotation_subspace()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
sage: WordMorphism('0->01,1->10').abelian_rotation_subspace()
```

(continues on next page)

(continued from previous page)

```
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
sage: WordMorphism('0->01,1->1').abelian_rotation_subspace()
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[0 1]
sage: WordMorphism('1->122,2->211').abelian_rotation_subspace()
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1]
sage: WordMorphism('0->1,1->102,2->3,3->4,4->2').abelian_rotation_subspace()
Vector space of degree 5 and dimension 3 over Rational Field
Basis matrix:
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

The domain needs to be equal to the codomain:

```
sage: WordMorphism('0->1,1->',codomain=Words('01')).abelian_rotation_
↪subspace()          # needs sage.modules
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
```

codomain()

Return the codomain of `self`.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').codomain()
Finite words over {'a', 'b'}
sage: WordMorphism('6->ab,y->5,0->asd').codomain()
Finite words over {'5', 'a', 'b', 'd', 's'}
```

conjugate(*pos*)

Return the morphism where the image of the letter by `self` is conjugated of parameter `pos`.

INPUT:

- `pos` – integer

EXAMPLES:

```
sage: m = WordMorphism('a->abcde')
sage: m.conjugate(0) == m
True
sage: m.conjugate(1)
WordMorphism: a->bcdea
sage: m.conjugate(3)
WordMorphism: a->deabc
sage: WordMorphism('').conjugate(4)
WordMorphism:
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.conjugate(2)
WordMorphism: a->cdeab, b->zxy
```

domain()

Return domain of `self`.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').domain()
Finite words over {'a', 'b'}
sage: WordMorphism('b->ba,a->ab').domain()
Finite words over {'a', 'b'}
sage: WordMorphism('6->ab,y->5,0->asd').domain()
Finite words over {'0', '6', 'y'}
```

dual_map(*k=1*)

Return the dual map E_k^* of self (see [1]).

Note: It is actually implemented only for $k = 1$.

INPUT:

- `self` – unimodular endomorphism defined on integers `1, 2, \ldots, d`
- `k` – integer (default: 1)

OUTPUT:

an instance of E1Star - the dual map

EXAMPLES:

```
sage: sigma = WordMorphism({1: [2], 2: [3], 3: [1,2]})
sage: sigma.dual_map()                                                      #␣
↪needs sage.modules
E_1^*(1->2, 2->3, 3->12)
```

```
sage: sigma.dual_map(k=2)
Traceback (most recent call last):
...
NotImplementedError: the dual map E_k^* is implemented only for k = 1 (not 2)
```

REFERENCES:

- [1] Sano, Y., Arnoux, P. and Ito, S., Higher dimensional extensions of substitutions and their dual maps, Journal d'Analyse Mathématique 83 (2001), 183-206.

extend_by(*other*)

Return `self` extended by `other`.

Let $\varphi_1 : A^* \to B^*$ and $\varphi_2 : C^* \to D^*$ be two morphisms. A morphism $\mu : (A \cup C)^* \to (B \cup D)^*$ corresponds to φ_1 *extended by* φ_2 if $\mu(a) = \varphi_1(a)$ if $a \in A$ and $\mu(a) = \varphi_2(a)$ otherwise.

INPUT:

- `other` – a WordMorphism.

OUTPUT:

WordMorphism

EXAMPLES:

```
sage: m = WordMorphism('a->ab,b->ba')
sage: n = WordMorphism({'0':'1','1':'0','a':'5'})
sage: m.extend_by(n)
WordMorphism: 0->1, 1->0, a->ab, b->ba
sage: n.extend_by(m)
WordMorphism: 0->1, 1->0, a->5, b->ba
sage: m.extend_by(m)
WordMorphism: a->ab, b->ba
```

fixed_point (*letter*)

Return the fixed point of `self` beginning by the given `letter`.

A fixed point of morphism φ is a word w such that $\varphi(w) = w$.

INPUT:

- `self` – an endomorphism (or more generally a self-composable morphism), must be prolongable on `letter`
- `letter` – in the domain of `self`, the first letter of the fixed point.

OUTPUT:

- `word` – the fixed point of `self` beginning with `letter`.

EXAMPLES:

```
sage: W = FiniteWords('abc')
```

1. Infinite fixed point:

```
sage: WordMorphism('a->ab,b->ba').fixed_point(letter='a')
word: abbabaabbaababbabaababbaabbabaabbaababba...
sage: WordMorphism('a->ab,b->a').fixed_point(letter='a')
word: abaababaabaababaababaabaababaabaababaaba...
sage: WordMorphism('a->ab,b->b,c->ba', codomain=W).fixed_point(letter='a')
word: abbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbb...
```

2. Infinite fixed point of an erasing morphism:

```
sage: WordMorphism('a->ab,b->,c->ba', codomain=W).fixed_point(letter='a')
word: ab
```

3. Finite fixed point:

```
sage: WordMorphism('a->ab,b->b,c->ba', codomain=W).fixed_point(letter='b')
word: b
sage: _.parent()
Finite words over {'a', 'b', 'c'}

sage: WordMorphism('a->ab,b->cc,c->', codomain=W).fixed_point(letter='a')
word: abcc
sage: _.parent()
Finite words over {'a', 'b', 'c'}

sage: m = WordMorphism('a->abc,b->,c->')
sage: fp = m.fixed_point('a'); fp
word: abc
```

(continues on next page)

(continued from previous page)

```
sage: m = WordMorphism('a->ba,b->')
sage: m('ba')
word: ba
sage: m.fixed_point('a') #todo: not implemented
word: ba
```

5. Fixed point of a power of a morphism:

```
sage: m = WordMorphism('a->ba,b->ab')
sage: (m^2).fixed_point(letter='a')
word: abbabaabbaababbabaababbaabbabaabbaababba...
```

6. With a self-composable but not endomorphism

   sage: m = WordMorphism('a->cbc,b->bc,c->b') sage: m.is_endomorphism() False sage: m.fixed_point('b') word: bcbbcbcbbcbbcbcbbcbcbbcbbcbcbbcbbcbcbbcb…

fixed_points()

Return the list of all fixed points of `self`.

EXAMPLES:

```
sage: f = WordMorphism('a->ab,b->ba')
sage: for w in f.fixed_points(): print(w)
abbabaabbaababbabaababbaabbabaabbaababba...
baababbaabbabaababbabaabbaababbaabbabaab...

sage: f = WordMorphism('a->ab,b->c,c->a')
sage: for w in f.fixed_points(): print(w)
abcaababcabcaabcaababcaababcabcaababcabc...

sage: f = WordMorphism('a->ab,b->cab,c->bcc')
sage: for w in f.fixed_points(): print(w)
abcabbccabcabcabbccbccabcabbccabcabbccab...
```

This shows that issue Issue #13668 has been resolved:

```
sage: d = {1:[1,2],2:[2,3],3:[4],4:[5],5:[6],6:[7],7:[8],8:[9],9:[10],10:[1]}
sage: s = WordMorphism(d)
sage: s7 = s^7
sage: s7.fixed_points()
[word: 12232342..., word: 2,3,4,5,6,7,8...]
sage: s7r = s7.reversal()
sage: s7r.periodic_point(2)
word: 2,1,1,10,9,8,7,6,5,4,3,2,1,10,9,8,7,6,5,4,3,2,10,9,8,7,6,5,4,3,2,9,8,7,
↪6,5,4,3,2,8,...
```

This shows that issue Issue #13668 has been resolved:

```
sage: s = "1->321331332133133,2->133321331332133133,3->
↪213313313332133133321331332133133"
sage: s = WordMorphism(s)
sage: (s^2).fixed_points()
[]
```

growing_letters()

Return the list of growing letters.

See *is_growing()* for more information.

EXAMPLES:

```
sage: WordMorphism('0->01,1->10').growing_letters()
['0', '1']
sage: WordMorphism('0->01,1->1').growing_letters()
['0']
sage: WordMorphism('0->01,1->0,2->1',codomain=Words('012')).growing_letters()
['0', '1', '2']
sage: WordMorphism('a->b,b->a').growing_letters()
[]
sage: WordMorphism('a->b,b->c,c->d,d->c', codomain=Words('abcd')).growing_
↪letters()
[]
```

has_conjugate_in_classP(*f=None*)

Return `True` if `self` has a conjugate in class f-P.

DEFINITION : Let A be an alphabet. We say that a primitive substitution S is in the *class P* if there exists a palindrome p and for each $b \in A$ a palindrome q_b such that $S(b) = pq_b$ for all $b \in A$. [1]

Let f be an involution on A. We say that a morphism φ is in class f-P if there exists an f-palindrome p and for each $\alpha \in A$ there exists an f-palindrome q_α such that $\varphi(\alpha) = pq_\alpha$. [2]

INPUT:

- `f` – involution (default: None) on the alphabet of `self`. It must be callable on letters as well as words (e.g. WordMorphism).

REFERENCES:

- [1] Hof, A., O. Knill et B. Simon, Singular continuous spectrum for palindromic Schrödinger operators, Commun. Math. Phys. 174 (1995) 149-159.
- [2] Labbe, Sebastien. Proprietes combinatoires des f-palindromes, Memoire de maitrise en Mathematiques, Montreal, UQAM, 2008, 109 pages.

EXAMPLES:

```
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.has_conjugate_in_classP()
True
sage: (fibo^2).is_in_classP()
False
sage: (fibo^2).has_conjugate_in_classP()
True
```

has_left_conjugate()

Return `True` if all the non empty images of `self` begins with the same letter.

EXAMPLES:

```
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_left_conjugate()
False
sage: WordMorphism('b->xyz').has_left_conjugate()
```

(continues on next page)

(continued from previous page)

```
True
sage: WordMorphism('').has_left_conjugate()
True
sage: WordMorphism('a->,b->xyz').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_left_conjugate()
True
```

has_right_conjugate()

Return `True` if all the non empty images of `self` ends with the same letter.

EXAMPLES:

```
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_right_conjugate()
False
sage: WordMorphism('b->xyz').has_right_conjugate()
True
sage: WordMorphism('').has_right_conjugate()
True
sage: WordMorphism('a->,b->xyz').has_right_conjugate()
True
sage: WordMorphism('a->abbab,b->abb').has_right_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_right_conjugate()
True
```

image(*letter*)

Return the image of a letter.

INPUT:

- `letter` – a letter in the domain alphabet

OUTPUT:

word

Note: The letter is assumed to be in the domain alphabet (no check done). Hence, this method is faster than the `__call__` method suitable for words input.

EXAMPLES:

```
sage: m = WordMorphism('a->ab,b->ac,c->a')
sage: m.image('b')
word: ac
```

```
sage: s = WordMorphism({('a', 1):[('a', 1), ('a', 2)], ('a', 2):[('a', 1)]})
sage: s.image(('a',1))
word: ('a', 1),('a', 2)
```

```
sage: s = WordMorphism({'b':[1,2], 'a':(2,3,4), 'z':[9,8,7]})
sage: s.image('b')
```

(continues on next page)

(continued from previous page)

```
word: 12
sage: s.image('a')
word: 234
sage: s.image('z')
word: 987
```

images()

Return the list of all the images of the letters of the alphabet under `self`.

EXAMPLES:

```
sage: sorted(WordMorphism('a->ab,b->a').images())
[word: a, word: ab]
sage: sorted(WordMorphism('6->ab,y->5,0->asd').images())
[word: 5, word: ab, word: asd]
```

immortal_letters()

Return the list of immortal letters.

A letter a is *immortal* for the morphism s if the length of the iterates of $|s^n(a)|$ is larger than zero as n goes to infinity.

Requires this morphism to be self-composable.

EXAMPLES:

```
sage: WordMorphism('a->a').immortal_letters()
['a']
sage: WordMorphism('a->b,b->a').immortal_letters()
['a', 'b']
sage: WordMorphism('a->abcd,b->cd,c->dd,d->').immortal_letters()
['a']
sage: WordMorphism('a->bc,b->cac,c->de,d->,e->').immortal_letters()
['a', 'b']
sage: WordMorphism('a->', domain=Words('a'), codomain=Words('a')).immortal_
↪letters()
[]

sage: WordMorphism('a->').immortal_letters()
[]
```

incidence_matrix()

Return the incidence matrix of the morphism. The order of the rows and column are given by the order defined on the alphabet of the domain and the codomain.

The matrix returned is over the integers. If a different ring is desired, use either the `change_ring` function or the `matrix` function.

EXAMPLES:

```
sage: m = WordMorphism('a->abc,b->a,c->c')
sage: m.incidence_matrix()                                                  #␣
↪needs sage.modules
[1 1 0]
[1 0 0]
[1 0 1]
sage: m = WordMorphism('a->abc,b->a,c->c,d->abbccccabca,e->abc')
```

(continues on next page)

(continued from previous page)

```
sage: m.incidence_matrix()                                                  #␣
↪needs sage.modules
[1 1 0 3 1]
[1 0 0 3 1]
[1 0 1 5 1]
```

infinite_repetitions_primitive_roots(*w=None*, *allow_growing=None*)

Return the set of primitive roots (up to conjugacy) of infinite repetitions from the language $\{m^n(w)|n \geq 0\}$, where m is this morphism and w is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

The word v^ω is an infinite repetition (in other words, an infinite periodic factor) of a language, if v is a non-empty word and for each positive integer k the word v^k is a factor of some word from the language. It turns out that a language created by iterating a morphism has a finite number of primitive roots of infinite repetitions.

If v is a primitive root of an infinite repetition, then all its conjugations are also primitive roots of an infinite repetition. For simplicity's sake this method returns only the lexicographically minimal one from each conjugacy class.

INPUT:

- `w` – finite iterable (default: `self.domain().alphabet()`). Represents a word used to start the language.
- `allow_growing` – boolean or `None` (default: `None`). If `False`, return only the primitive roots that contain no growing letters. If `True`, return only the primitive roots that contain at least one growing letter. If `None`, return both.

ALGORITHM:

The algorithm used is described in detail in [KS2015].

EXAMPLES:

```
sage: m = WordMorphism('a->aba,b->aba,c->cd,d->e,e->d')
sage: inf_reps = m.infinite_repetitions_primitive_roots('ac')
sage: sorted(inf_reps)
[word: aab, word: de]
```

`allow_growing` parameter:

```
sage: sorted(m.infinite_repetitions_primitive_roots('ac', True))
[word: aab]
sage: sorted(m.infinite_repetitions_primitive_roots('ac', False))
[word: de]
```

Incomplete check that these words are indeed the primitive roots of infinite repetitions:

```
sage: SL = m._language_naive(10, Word('ac'))
sage: all(x in SL for x in inf_reps)
True
sage: all(x^2 in SL for x in inf_reps)
True
sage: all(x^3 in SL for x in inf_reps)
True
```

Large example:

```
sage: m = WordMorphism('a->1b5,b->fcg,c->dae,d->432,e->678,f->f,g->g,1->2,2->
↪3,3->4,4->1,5->6,6->7,7->8,8->5')
sage: sorted(m.infinite_repetitions_primitive_roots('a'))
[word: 1432f2143f3214f4321f, word: 5678g8567g7856g6785g]
```

is_empty()

Return `True` if the cardinality of the domain is zero and `False` otherwise.

EXAMPLES:

```
sage: WordMorphism('').is_empty()
True
sage: WordMorphism('a->a').is_empty()
False
```

is_endomorphism()

Return whether `self` is an endomorphism, that is if the domain coincide with the codomain.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').is_endomorphism()
True
sage: WordMorphism('6->ab,y->5,0->asd').is_endomorphism()
False
sage: WordMorphism('a->a,b->aa,c->aaa').is_endomorphism()
False
sage: Wabc = Words('abc')
sage: m = WordMorphism('a->a,b->aa,c->aaa',codomain = Wabc)
sage: m.is_endomorphism()
True
```

We check that Issue #8674 is fixed:

```
sage: P = WordPaths('abcd')                                                    #␣
↪needs sage.modules
sage: m = WordMorphism('a->adab,b->ab,c->cbcd,d->cd',                          #␣
↪needs sage.modules
....:                   domain=P, codomain=P)
sage: m.is_endomorphism()                                                      #␣
↪needs sage.modules
True
```

is_erasing()

Return `True` if `self` is an erasing morphism, i.e. the image of a letter is the empty word.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd,7->').is_erasing()
True
sage: WordMorphism('').is_erasing()
False
```

is_growing(*letter=None*)

Return `True` if `letter` is a growing letter.

A letter a is *growing* for the morphism s if the length of the iterates of $|s^n(a)|$ tend to infinity as n goes to infinity.

INPUT:

- `letter` – `None` or a letter in the domain of `self`

Note: If letter is `None`, this returns `True` if `self` is everywhere growing, i.e., all letters are growing letters (see [CassNic10]), and that `self` **must** be an endomorphism.

EXAMPLES:

```
sage: WordMorphism('0->01,1->1').is_growing('0')
True
sage: WordMorphism('0->01,1->1').is_growing('1')
False
sage: WordMorphism('0->01,1->10').is_growing()
True
sage: WordMorphism('0->1,1->2,2->01').is_growing()
True
sage: WordMorphism('0->01,1->1').is_growing()
False
```

The domain needs to be equal to the codomain:

```
sage: WordMorphism('0->01,1->0,2->1',codomain=Words('012')).is_growing()
True
```

Test of erasing morphisms:

```
sage: WordMorphism('0->01,1->').is_growing('0')
False
sage: m = WordMorphism('a->bc,b->bcc,c->',codomain=Words('abc'))
sage: m.is_growing('a')
False
sage: m.is_growing('b')
False
sage: m.is_growing('c')
False
```

REFERENCES:

is_identity()

Return `True` if `self` is the identity morphism.

EXAMPLES:

```
sage: m = WordMorphism('a->a,b->b,c->c,d->e')
sage: m.is_identity()
False
sage: WordMorphism('a->a,b->b,c->c').is_identity()
True
sage: WordMorphism('a->a,b->b,c->cb').is_identity()
False
sage: m = WordMorphism('a->b,b->c,c->a')
sage: (m^2).is_identity()
False
```

(continues on next page)

(continued from previous page)

```
sage: (m^3).is_identity()
True
sage: (m^4).is_identity()
False
sage: WordMorphism('').is_identity()
True
sage: WordMorphism({0:[0],1:[1]}).is_identity()
True
```

We check that Issue #8618 is fixed:

```
sage: t = WordMorphism({'a1':['a2'], 'a2':['a1']})
sage: (t*t).is_identity()
True
```

is_in_classP (*f=None*)

Return `True` if `self` is in class P (or f-P).

DEFINITION : Let A be an alphabet. We say that a primitive substitution S is in the *class P* if there exists a palindrome p and for each $b \in A$ a palindrome q_b such that $S(b) = pq_b$ for all $b \in A$. [1]

Let f be an involution on A. "We say that a morphism φ is in class f-P if there exists an f-palindrome p and for each $\alpha \in A$ there exists an f-palindrome q_α such that $\varphi(\alpha) = pq_\alpha$. [2]

INPUT:

- `f` – involution (default: None) on the alphabet of `self`. It must be callable on letters as well as words (e.g. WordMorphism).

REFERENCES:

- [1] Hof, A., O. Knill et B. Simon, Singular continuous spectrum for palindromic Schrödinger operators, Commun. Math. Phys. 174 (1995) 149-159.
- [2] Labbe, Sebastien. Proprietes combinatoires des f-palindromes, Memoire de maitrise en Mathematiques, Montreal, UQAM, 2008, 109 pages.

EXAMPLES:

```
sage: WordMorphism('a->bbaba,b->bba').is_in_classP()
True
sage: tm = WordMorphism('a->ab,b->ba')
sage: tm.is_in_classP()
False
sage: f = WordMorphism('a->b,b->a')
sage: tm.is_in_classP(f=f)
True
sage: (tm^2).is_in_classP()
True
sage: (tm^2).is_in_classP(f=f)
False
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.is_in_classP()
True
sage: fibo.is_in_classP(f=f)
False
sage: (fibo^2).is_in_classP()
False
sage: f = WordMorphism('a->b,b->a,c->c')
```

(continues on next page)

(continued from previous page)

```
sage: WordMorphism('a->acbcc,b->acbab,c->acbba').is_in_classP(f)
True
```

is_injective()

Return whether this morphism is injective.

ALGORITHM:

Uses a version of Wikipedia article Sardinas–Patterson_algorithm. Time complexity is on average quadratic with regards to the size of the morphism.

EXAMPLES:

```
sage: WordMorphism('a->0,b->10,c->110,d->111').is_injective()
True
sage: WordMorphism('a->00,b->01,c->012,d->20001').is_injective()
False
```

is_involution()

Return `True` if `self` is an involution, i.e. its square is the identity.

INPUT:

- `self` – an endomorphism

EXAMPLES:

```
sage: WordMorphism('a->b,b->a').is_involution()
True
sage: WordMorphism('a->b,b->ba').is_involution()
False
sage: WordMorphism({0:[1],1:[0]}).is_involution()
True
```

is_primitive()

Return `True` if `self` is primitive.

A morphism φ is *primitive* if there exists an positive integer k such that for all $\alpha \in \Sigma$, $\varphi^k(\alpha)$ contains all the letters of Σ.

INPUT:

- `self` – an endomorphism

ALGORITHM:

> Exercices 8.7.8, p.281 in [1]: (c) Let $y(M)$ be the least integer e such that M^e has all positive entries. Prove that, for all primitive matrices M, we have $y(M) \leq (d-1)^2 + 1$. (d) Prove that the bound $y(M) \leq (d-1)^2 + 1$ is best possible.

EXAMPLES:

```
sage: tm = WordMorphism('a->ab,b->ba')

↪needs sage.modules
True
```

REFERENCES:

- [1] Jean-Paul Allouche and Jeffrey Shallit, Automatic Sequences: Theory, Applications, Generalizations, Cambridge University Press, 2003.

is_prolongable(*letter*)

Return `True` if `self` is prolongable on `letter`.

A morphism φ is prolongable on a letter a if a is a prefix of $\varphi(a)$.

INPUT:

- `self` – its codomain must be an instance of Words
- `letter` – a letter in the domain alphabet

OUTPUT:

Boolean

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='a')
True
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='b')
False
sage: WordMorphism('a->ba,b->ab').is_prolongable(letter='b')
False
sage: (WordMorphism('a->ba,b->ab')^2).is_prolongable(letter='b')
True
sage: WordMorphism('a->ba,b->').is_prolongable(letter='b')
False
sage: WordMorphism('a->bb,b->aac').is_prolongable(letter='a')
False
```

We check that Issue #8595 is fixed:

```
sage: s = WordMorphism({('a', 1) : [('a', 1), ('a', 2)], ('a', 2) : [('a',␣
↪1)]})
```

(continues on next page)

(continued from previous page)

```
sage: s.is_prolongable(('a',1))
True
```

is_pushy(*w=None*)

Return whether the language $\{m^n(w)|n \geq 0\}$ is pushy, where m is this morphism and w is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

A language created by iterating a morphism is pushy, if its words contain an infinite number of factors containing no growing letters. It turns out that this is equivalent to having at least one infinite repetition containing no growing letters.

See *infinite_repetitions_primitive_roots()* and *is_growing()*.

INPUT:

- `w` – finite iterable (default: `self.domain().alphabet()`). Represents a word used to start the language.

EXAMPLES:

```
sage: WordMorphism('a->abca,b->bc,c->').is_pushy()
False
sage: WordMorphism('a->abc,b->,c->bcb').is_pushy()
True
```

is_repetitive(*w=None*)

Return whether the language $\{m^n(w)|n \geq 0\}$ is repetitive, where m is this morphism and w is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

A language is repetitive, if for each positive integer k there exists a word u such that u^k is a factor of some word of the language.

It turns out that for languages created by iterating a morphism this is equivalent to having at least one infinite repetition (this property is also known as strong repetitiveness).

See *infinite_repetitions_primitive_roots()*.

INPUT:

- `w` – finite iterable (default: `self.domain().alphabet()`). Represents a word used to start the language.

EXAMPLES:

This method can be used to check whether a purely morphic word is not k-power free for all positive integers k. For example, the language containing just the Thue-Morse word and its prefixes is not repetitive, since the Thue-Morse word is cube-free:

```
sage: WordMorphism('a->ab,b->ba').is_repetitive('a')
False
```

Similarly, the Hanoi word is square-free:

```
sage: WordMorphism('a->aC,A->ac,b->cB,B->cb,c->bA,C->ba').is_repetitive('a')
False
```

However, this method solves a more general problem, as it can be called on any morphism m and with any word w:

```
sage: WordMorphism('a->c,b->cda,c->a,d->abc').is_repetitive('bd')
True
```

is_self_composable()

Return whether the codomain of `self` is contained in the domain.

EXAMPLES:

```
sage: f = WordMorphism('a->a,b->a')
sage: f.is_endomorphism()
False
sage: f.is_self_composable()
True
```

is_unboundedly_repetitive(*w=None*)

Return whether the language $\{m^n(w)|n \geq 0\}$ is unboundedly repetitive, where m is this morphism and w is a word inputted as a parameter.

Requires this morphism to be an endomorphism.

A language created by iterating a morphism is unboundedly repetitive, if it has at least one infinite repetition containing at least one growing letter.

See *infinite_repetitions_primitive_roots()* and *is_growing()*.

INPUT:

- `w` – finite iterable (default: `self.domain().alphabet()`). Represents a word used to start the language.

EXAMPLES:

```
sage: WordMorphism('a->abca,b->bc,c->').is_unboundedly_repetitive()
True
sage: WordMorphism('a->abc,b->,c->bcb').is_unboundedly_repetitive()
False
```

is_uniform(*k=None*)

Return `True` if `self` is a k-uniform morphism.

Let k be a positive integer. A morphism ϕ is called k-uniform if for every letter α, we have $|\phi(\alpha)| = k$. In other words, all images have length k. A morphism is called uniform if it is k-uniform for some positive integer k.

INPUT:

- `k` – a positive integer or `None`. If set to a positive integer, then the function return `True` if `self` is k-uniform. If set to `None`, then the function return `True` if `self` is uniform.

EXAMPLES:

```
sage: phi = WordMorphism('a->ab,b->a')
sage: phi.is_uniform()
False
sage: phi.is_uniform(k=1)
False
sage: tau = WordMorphism('a->ab,b->ba')
```

(continues on next page)

(continued from previous page)

```
sage: tau.is_uniform()
True
sage: tau.is_uniform(k=1)
False
sage: tau.is_uniform(k=2)
True
```

language(*n*, *u=None*)

Return the words of length `n` in the language generated by this substitution.

Given a non-erasing substitution s and a word u the DOL-language generated by s and u is the union of the factors of $s^n(u)$ where n is a non-negative integer.

INPUT:

- `n` – non-negative integer; length of the words in the language
- `u` – a word or `None` (default: `None`); if set to `None` some letter of the alphabet is used

OUTPUT: a Python set

EXAMPLES:

The fibonacci morphism:

```
sage: s = WordMorphism({0: [0,1], 1: [0]})
sage: sorted(s.language(3))                                                 #␣
↪needs sage.modules
[word: 001, word: 010, word: 100, word: 101]
sage: len(s.language(1000))                                                 #␣
↪needs sage.modules
1001
sage: all(len(s.language(n)) == n+1 for n in range(100))                    #␣
↪needs sage.modules
True
```

A growing but non-primitive example. The DOL-languages generated by 0 and 2 are different:

```
sage: s = WordMorphism({0: [0,1], 1: [0], 2: [2,0,2]})

sage: u = s.fixed_point(0)
sage: A0 = u[:200].factor_set(5)                                            #␣
↪needs sage.modules
sage: B0 = s.language(5, [0])                                               #␣
↪needs sage.modules
sage: set(A0) == B0                                                         #␣
↪needs sage.modules
True

sage: v = s.fixed_point(2)
sage: A2 = v[:200].factor_set(5)                                            #␣
↪needs sage.modules
sage: B2 = s.language(5, [2])                                               #␣
↪needs sage.modules
sage: set(A2) == B2                                                         #␣
↪needs sage.modules
True

sage: len(A0), len(A2)                                                      #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules
(6, 20)
```

The Chacon transformation (non-primitive):

```
sage: s = WordMorphism({0: [0,0,1,0], 1:[1]})
sage: sorted(s.language(10))                                                #␣
↪needs sage.modules
[word: 0001000101,
 word: 0001010010,
 ...
 word: 1010010001,
 word: 1010010100]
```

latex_layout (*layout=None*)

Get or set the actual latex layout (oneliner vs array).

INPUT:

- `layout` – string (default: `None`), can take one of the following values:
  - `None` – Returns the actual latex layout. By default, the layout is `'array'`
  - `'oneliner'` – Set the layout to `'oneliner'`
  - `'array'` – Set the layout to `'array'`

EXAMPLES:

```
sage: s = WordMorphism('a->ab,b->ba')
sage: s.latex_layout()
'array'
sage: s.latex_layout('oneliner')
sage: s.latex_layout()
'oneliner'
```

letter_growth_types()

Return the mortal, polynomial and exponential growing letters.

The growth of $|s^n(a)|$ as n goes to ∞ is always of the form $\alpha^n n^\beta$ (where α is a Perron number and β an integer).

Without doing any linear algebra three cases can be differentiated: mortal (ultimately empty or $\alpha = 0$); polynomial ($\alpha = 1$); exponential ($\alpha > 1$). This is what is done in this method.

It requires this morphism to be an endomorphism.

OUTPUT:

The output is a 3-tuple of lists (mortal, polynomial, exponential) where:

- `mortal`: list of mortal letters
- `polynomial`: a list of lists where `polynomial[i]` is the list of letters with growth n^i.
- `exponential`: list of at least exponentionally growing letters

EXAMPLES:

```
sage: s = WordMorphism('a->abc,b->bc,c->c')
sage: mortal, poly, expo = s.letter_growth_types()
sage: mortal
[]
sage: poly
[['c'], ['b'], ['a']]
sage: expo
[]
```

When three mortal letters (c, d, and e), and two letters (a, b) are not growing:

```
sage: s = WordMorphism('a->bc,b->cac,c->de,d->,e->')
sage: s^20
WordMorphism: a->cacde, b->debcde, c->, d->, e->
sage: mortal, poly, expo = s.letter_growth_types()
sage: mortal
['c', 'd', 'e']
sage: poly
[['a', 'b']]
sage: expo
[]
```

```
sage: s = WordMorphism('a->abcd,b->bc,c->c,d->a')
sage: mortal, poly, expo = s.letter_growth_types()
sage: mortal
[]
sage: poly
[['c'], ['b']]
sage: expo
['a', 'd']
```

list_of_conjugates()

Return the list of all the conjugate morphisms of `self`.

DEFINITION:

Recall from Lothaire [1] (Section 2.3.4) that φ is *right conjugate* of φ', noted $\varphi \triangleleft \varphi'$, if there exists $u \in \Sigma^*$ such that

$$\varphi(\alpha)u = u\varphi'(\alpha),$$

for all $\alpha \in \Sigma$, or equivalently that $\varphi(x)u = u\varphi'(x)$, for all words $x \in \Sigma^*$. Clearly, this relation is not symmetric so that we say that two morphisms φ and φ' are *conjugate*, noted $\varphi \bowtie \varphi'$, if $\varphi \triangleleft \varphi'$ or $\varphi' \triangleleft \varphi$. It is easy to see that conjugacy of morphisms is an equivalence relation.

REFERENCES:

- [1] M. Lothaire, Algebraic Combinatorics on words, Cambridge University Press, 2002.

EXAMPLES:

```
sage: m = WordMorphism('a->abbab,b->abb')
sage: m.list_of_conjugates()
[WordMorphism: a->babba, b->bab,
WordMorphism: a->abbab, b->abb,
WordMorphism: a->bbaba, b->bba,
WordMorphism: a->babab, b->bab,
WordMorphism: a->ababb, b->abb,
```

(continues on next page)

(continued from previous page)

```
WordMorphism: a->babba, b->bba,
WordMorphism: a->abbab, b->bab]
sage: m = WordMorphism('a->aaa,b->aa')
sage: m.list_of_conjugates()
[WordMorphism: a->aaa, b->aa]
sage: WordMorphism('').list_of_conjugates()
[WordMorphism: ]
sage: m = WordMorphism('a->aba,b->aba')
sage: m.list_of_conjugates()
[WordMorphism: a->baa, b->baa,
WordMorphism: a->aab, b->aab,
WordMorphism: a->aba, b->aba]
sage: m = WordMorphism('a->abb,b->abbab,c->')
sage: m.list_of_conjugates()
[WordMorphism: a->bab, b->babba, c->,
WordMorphism: a->abb, b->abbab, c->,
WordMorphism: a->bba, b->bbaba, c->,
WordMorphism: a->bab, b->babab, c->,
WordMorphism: a->abb, b->ababb, c->,
WordMorphism: a->bba, b->babba, c->,
WordMorphism: a->bab, b->abbab, c->]
```

partition_of_domain_alphabet()

Return a partition of the domain alphabet.

Let $\varphi : \Sigma^* \to \Sigma^*$ be an involution. There exists a triple of sets (A, B, C) such that

- $A \cup B \cup C = \Sigma$;
- A, B and C are mutually disjoint and
- $\varphi(A) = B, \varphi(B) = A, \varphi(C) = C$.

These sets are not unique.

INPUT:

- `self` – An involution.

OUTPUT:

A tuple of three sets

EXAMPLES:

```
sage: m = WordMorphism('a->b,b->a')
sage: m.partition_of_domain_alphabet()  # random ordering
({'a'}, {'b'}, {})
sage: m = WordMorphism('a->b,b->a,c->c')
sage: m.partition_of_domain_alphabet()  # random ordering
({'a'}, {'b'}, {'c'})
sage: m = WordMorphism('a->a,b->b,c->c')
sage: m.partition_of_domain_alphabet()  # random ordering
({}, {}, {'a', 'c', 'b'})
sage: m = WordMorphism('A->T,T->A,C->G,G->C')
sage: m.partition_of_domain_alphabet()  # random ordering
({'A', 'C'}, {'T', 'G'}, {})
sage: I = WordMorphism({0:oo,oo:0,1:-1,-1:1,2:-2,-2:2,3:-3,-3:3})
sage: I.partition_of_domain_alphabet()  # random ordering
({0, -1, -3, -2}, {1, 2, 3, +Infinity}, {})
```

periodic_point(*letter*)

Return the periodic point of self that starts with `letter`.

EXAMPLES:

```
sage: f = WordMorphism('a->bab,b->ab')
sage: f.periodic_point('a')
word: abbababbababbababbababbababbababbababbaba...
sage: f.fixed_point('a')
Traceback (most recent call last):
...
TypeError: self must be prolongable on a
```

Make sure that Issue #31759 is fixed:

```
sage: WordMorphism('a->b,b->a').periodic_point('a')
word: a
```

periodic_points()

Return the periodic points of `f` as a list of tuples where each tuple is a periodic orbit of `f`.

EXAMPLES:

```
sage: f = WordMorphism('a->aba,b->baa')
sage: for p in f.periodic_points():
....:     print("{} , {}".format(len(p), p[0]))
1 , ababaaababaaabaabaababaaababaaabaabaabab...
1 , baaabaabaababaaabaababaaabaababaaababaaa...

sage: f = WordMorphism('a->bab,b->aa')
sage: for p in f.periodic_points():
....:     print("{} , {}".format(len(p), p[0]))
2 , aababaaaababaabababbabaababaabababbabaababaa...
sage: f.fixed_points()
[]
```

This shows that issue Issue #13668 has been resolved:

```
sage: d = {1:[1,2],2:[2,3],3:[4],4:[5],5:[6],6:[7],7:[8],8:[9],9:[10],10:[1]}
sage: s = WordMorphism(d)
sage: s7 = s^7
sage: s7r = s7.reversal()
sage: for p in s7r.periodic_points(): p
[word: 1,10,9,8,7,6,5,4,3,2,10,9,8,7,6,5,4,3,2,...,
 word: 876543276543265432543243232176543265432...,
 word: 5,4,3,2,4,3,2,3,2,2,1,4,3,2,3,2,2,1,3,2,...,
 word: 2,1,1,10,9,8,7,6,5,4,3,2,1,10,9,8,7,6,5,...,
 word: 98765432876543276543265432543243232221876...,
 word: 65432543243232215432432322143232213221121...,
 word: 3,2,2,1,2,1,1,10,9,8,7,6,5,4,3,2,2,1,1,1...,
 word: 10,9,8,7,6,5,4,3,2,9,8,7,6,5,4,3,2,8,7,6...,
 word: 765432654325432432322165432543243232215 4...,
 word: 4,3,2,3,2,2,1,3,2,2,1,2,1,1,10,9,8,7,6,5...]
```

Make sure that Issue #31454 is fixed:

```
sage: WordMorphism('a->a,b->bb').periodic_points()
[[word: bbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbb...]]
```

pisot_eigenvector_left()

Return the left eigenvector of the incidence matrix associated to the largest eigenvalue (in absolute value).

Unicity of the result is guaranteed when the multiplicity of the largest eigenvalue is one, for example when self is a Pisot irreductible substitution.

A substitution is Pisot irreducible if the characteristic polynomial of its incidence matrix is irreducible over **Q** and has all roots, except one, of modulus strictly smaller than 1.

INPUT:

- `self` – a Pisot irreducible substitution.

EXAMPLES:

```
sage: m = WordMorphism('a->aaaabbc,b->aaabbc,c->aabc')
sage: matrix(m)                                                             #␣
↪needs sage.modules
[4 3 2]
[2 2 1]
[1 1 1]
sage: m.pisot_eigenvector_left()                                            #␣
↪needs sage.modules sage.rings.number_field
(1, 0.8392867552141611?, 0.5436890126920763?)
```

pisot_eigenvector_right()

Return the right eigenvector of the incidence matrix associated to the largest eigenvalue (in absolute value).

Unicity of the result is guaranteed when the multiplicity of the largest eigenvalue is one, for example when self is a Pisot irreductible substitution.

A substitution is Pisot irreducible if the characteristic polynomial of its incidence matrix is irreducible over **Q** and has all roots, except one, of modulus strictly smaller than 1.

INPUT:

- `self` – a Pisot irreducible substitution.

EXAMPLES:

```
sage: m = WordMorphism('a->aaaabbc,b->aaabbc,c->aabc')
sage: matrix(m)                                                             #␣
↪needs sage.modules
[4 3 2]
[2 2 1]
[1 1 1]
sage: m.pisot_eigenvector_right()                                           #␣

```

rauzy_fractal_plot(*n=None*, *exchange=False*, *eig=None*, *translate=None*, *prec=53*, *colormap='hsv'*, *opacity=None*, *plot_origin=None*, *plot_basis=False*, *point_size=None*)

Return a plot of the Rauzy fractal associated with a substitution.

The substitution does not have to be irreducible. The usual definition of a Rauzy fractal requires that its dominant eigenvalue is a Pisot number but the present method doesn't require this, allowing to plot some interesting pictures in the non-Pisot case (see the examples below).

For more details about the definition of the fractal and the projection which is used, see Section 3.1 of [1].

Plots with less than 100,000 points take a few seconds, and several millions of points can be plotted in reasonable time.

Other ways to draw Rauzy fractals (and more generally projections of paths) can be found in *sage.combinat.words.paths.FiniteWordPath_all.plot_projection()* or in *sage.combinat.e_one_star()*.

OUTPUT:

A Graphics object.

INPUT:

- `n` – integer (default: `None`) The number of points used to plot the fractal. Default values: `1000` for a 1D fractal, `50000` for a 2D fractal, `10000` for a 3D fractal.
- `exchange` – boolean (default: `False`). Plot the Rauzy fractal with domain exchange.
- `eig` – a real element of `QQbar` of degree >= 2 (default: `None`). The eigenvalue used to plot the fractal. It must be an eigenvalue of `self.incidence_matrix()`. The one used by default the maximal eigenvalue of `self.incidence_matrix()` (usually a Pisot number), but for substitutions with more than 3 letters other interesting choices are sometimes possible.
- `translate` – a list of vectors of `RR^size_alphabet`, or a dictionary from the alphabet to lists of vectors (default: `None`). Plot translated copies of the fractal. This option allows to plot tilings easily. The projection used for these vectors is the same as the projection used for the canonical basis to plot the fractal. If the input is a list, all the pieces will be translated and plotted. If the input is a dictionary, each piece will be translated and plotted accordingly to the vectors associated with each letter in the dictionary. Note: by default, the Rauzy fractal placed at the origin is not plotted with the `translate` option; the vector `(0,0,...,0)` has to be added manually.
- `prec` – integer (default: `53`). The number of bits used in the floating point representations of the points of the fractal.
- `colormap` – color map or dictionary (default: `'hsv'`). It can be one of the following:
  - `string` – a coloring map. For available coloring map names type: `sorted(colormaps)`
  - `dict` – a dictionary of the alphabet mapped to colors.
- `opacity` – a dictionary from the alphabet to the real interval [0,1] (default: `None`). If none is specified, all letters are plotted with opacity `1`.
- `plot_origin` – a couple `(k,c)` (default: `None`). If specified, mark the origin by a point of size `k` and color `c`.
- `plot_basis` – boolean (default: `False`). Plot the projection of the canonical basis with the fractal.
- `point_size` – float (default: `None`). The size of the points used to plot the fractal.

EXAMPLES:

1. The Rauzy fractal of the Tribonacci substitution:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_plot()        # long time
↪  # needs sage.plot
Graphics object consisting of 3 graphics primitives
```

2. The "Hokkaido" fractal. We tweak the plot using the plotting options to get a nice reusable picture, in which we mark the origin by a black dot:

```
sage: s = WordMorphism('a->ab,b->c,c->d,d->e,e->a')
sage: G = s.rauzy_fractal_plot(n=100000, point_size=3,          # not
↪tested
```

(continues on next page)

(continued from previous page)

```
....:                           plot_origin=(50,"black"))
sage: G.show(figsize=10, axes=false) # not tested
```

3. Another "Hokkaido" fractal and its domain exchange:

```
sage: s = WordMorphism({1:[2], 2:[4,3], 3:[4], 4:[5,3], 5:[6], 6:[1]})
sage: s.rauzy_fractal_plot()                                    # not␣
↪tested (> 1 second)
sage: s.rauzy_fractal_plot(exchange=True)                       # not␣
↪tested (> 1 second)
```

4. A three-dimensional Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->14,4->1')
sage: s.rauzy_fractal_plot()                                    # not␣
↪tested (> 1 second)
```

5. A one-dimensional Rauzy fractal (very scattered):

```
sage: s = WordMorphism('1->2122,2->1')
sage: s.rauzy_fractal_plot().show(figsize=20)                   # not␣
↪tested (> 1 second)
```

6. A high resolution plot of a complicated fractal:

```
sage: s = WordMorphism('1->23,2->123,3->1122233')
sage: G = s.rauzy_fractal_plot(n=300000)                        # not␣
↪tested (> 1 second)
sage: G.show(axes=false, figsize=20)                            # not␣
↪tested (> 1 second)
```

7. A nice colorful animation of a domain exchange:

```
sage: s = WordMorphism('1->21,2->3,3->4,4->25,5->6,6->7,7->1')
sage: L = [s.rauzy_fractal_plot(),                              # not␣
↪tested (> 1 second)
....:      s.rauzy_fractal_plot(exchange=True)]
sage: animate(L, axes=false).show(delay=100)                    # not␣
↪tested (> 1 second)
```

8. Plotting with only one color:

```
sage: s = WordMorphism('1->12,2->31,3->1')
sage: cm = {'1':'black', '2':'black', '3':'black'}
sage: s.rauzy_fractal_plot(colormap=cm)                         # not␣
↪tested (> 1 second)
```

9. Different fractals can be obtained by choosing another (non-Pisot) eigenvalue:

```
sage: s = WordMorphism('1->12,2->3,3->45,4->5,5->6,6->7,7->8,8->1')
sage: E = s.incidence_matrix().eigenvalues()                    ␣
↪  # needs sage.modules
sage: x = [x for x in E if -0.8 < x < -0.7][0]                  ␣
↪  # needs sage.modules
sage: s.rauzy_fractal_plot()                                    # not␣
↪tested (> 1 second)
```

(continues on next page)

(continued from previous page)

```
sage: s.rauzy_fractal_plot(eig=x)                                    # not␣
↪tested (> 1 second)
```

10. A Pisot reducible substitution with seemingly overlapping tiles:

```
sage: s = WordMorphism({1:[1,2], 2:[2,3], 3:[4], 4:[5], 5:[6],
....:                   6:[7], 7:[8], 8:[9], 9:[10], 10:[1]})
sage: s.rauzy_fractal_plot()                                         # not␣
↪tested (> 1 second)
```

11. A non-Pisot reducible substitution with a strange Rauzy fractal:

```
sage: s = WordMorphism({1:[3,2], 2:[3,3], 3:[4], 4:[1]})
sage: s.rauzy_fractal_plot()                                         # not␣
↪tested (> 1 second)
```

12. A substitution with overlapping tiles. We use the options `colormap` and `opacity` to study how the tiles overlap:

```
sage: s = WordMorphism('1->213,2->4,3->5,4->1,5->21')
sage: s.rauzy_fractal_plot()                                         # not␣
↪tested (> 1 second)
sage: s.rauzy_fractal_plot(colormap={'1':'red', '4':'purple'})       # not␣
↪tested (> 1 second)
sage: s.rauzy_fractal_plot(n=150000,                                 # not␣
↪tested (> 1 second)
....:                      opacity={'1':0.1,'2':1,'3':0.1,'4':0.1,'5':0.1}
↪)
```

13. Funny experiments by playing with the precision of the float numbers used to plot the fractal:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_plot(prec=6)                                   # not␣
↪tested
sage: s.rauzy_fractal_plot(prec=9)                                   # not␣
↪tested
sage: s.rauzy_fractal_plot(prec=15)                                  # not␣
↪tested
sage: s.rauzy_fractal_plot(prec=19)                                  # not␣
↪tested
sage: s.rauzy_fractal_plot(prec=25)                                  # not␣
↪tested
```

14. Using the `translate` option to plot periodic tilings:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_plot(n=10000,                                  # not␣
↪tested (> 1 second)
....:                      translate=[(0,0,0),(-1,0,1),(0,-1,1),(1,-1,0),
....:                                 (1,0,-1),(0,1,-1),(-1,1,0)])
```

```
sage: t = WordMorphism("a->aC,b->d,C->de,d->a,e->ab")    # substitution␣
↪found by Julien Bernat
sage: V = [vector((0,0,1,0,-1)), vector((0,0,1,-1,0))]                ␣
↪  # needs sage.modules
sage: S = set(map(tuple, [i*V[0] + j*V[1]                             ␣
```

(continues on next page)

(continued from previous page)

```
↪  # needs sage.modules
....:                     for i in [-1,0,1] for j in [-1,0,1]]))
sage: t.rauzy_fractal_plot(n=10000,                                  # not␣
↪tested (> 1 second)
....:                      translate=S, exchange=true)
```

15. Using the `translate` option to plot arbitrary tilings with the fractal pieces. This can be used for example to plot the self-replicating tiling of the Rauzy fractal:

```
sage: s = WordMorphism({1:[1,2], 2:[3], 3:[4,3], 4:[5], 5:[6], 6:[1]})
sage: s.rauzy_fractal_plot()                                         # not␣
↪tested (> 1 second)
sage: D = {1: [(0,0,0,0,0,0), (0,1,0,0,0,0)],
....:      3: [(0,0,0,0,0,0), (0,1,0,0,0,0)], 6: [(0,1,0,0,0,0)]}
sage: s.rauzy_fractal_plot(n=30000, translate=D)                      # not␣
↪tested (> 1 second)
```

16. Plot the projection of the canonical basis with the fractal:

```
sage: s = WordMorphism({1:[2,1], 2:[3], 3:[6,4], 4:[5,1],
....:                   5:[6], 6:[7], 7:[8], 8:[9], 9:[1]})
sage: s.rauzy_fractal_plot(plot_basis=True)                          # not␣
↪tested (> 1 second)
```

rauzy_fractal_points (*n=None*, *exchange=False*, *eig=None*, *translate=None*, *prec=53*)

Return a dictionary of list of points associated with the pieces of the Rauzy fractal of `self`.

INPUT:

See the method *`rauzy_fractal_plot()`* for a description of the options and more examples.

OUTPUT:

dictionary of list of points

EXAMPLES:

The Rauzy fractal of the Tribonacci substitution and the number of points in the piece of the fractal associated with `'1'`, `'2'` and `'3'` are respectively:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.rauzy_fractal_points(n=100)                                #␣
↪needs sage.modules
sage: len(D['1'])                                                      #␣
↪needs sage.modules
54
sage: len(D['2'])                                                      #␣
↪needs sage.modules
30
sage: len(D['3'])                                                      #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules
16
```

AUTHOR:

Timo Jolivet (2012-06-16)

rauzy_fractal_projection(*eig=None*, *prec=53*)

Return a dictionary giving the projection of the canonical basis.

See the method *rauzy_fractal_plot()* for more details about the projection.

INPUT:

- `eig` – a real element of `QQbar` of degree >= 2 (default: `None`). The eigenvalue used for the projection. It must be an eigenvalue of `self.incidence_matrix()`. The one used by default is the maximal eigenvalue of `self.incidence_matrix()` (usually a Pisot number), but for substitutions with more than 3 letters other interesting choices are sometimes possible.
- `prec` – integer (default: `53`). The number of bits used in the floating point representations of the coordinates.

OUTPUT:

dictionary, letter -> vector, giving the projection

EXAMPLES:

The projection for the Rauzy fractal of the Tribonacci substitution is:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_projection()                                          #␣
↪needs sage.modules
{'1': (1.00000000000000, 0.000000000000000),
 '2': (-1.41964337760708, -0.606290729207199),
 '3': (-0.771844506346038, 1.11514250803994)}
```

AUTHOR:

Timo Jolivet (2012-06-16)

restrict_domain(*alphabet*)

Return a restriction of `self` to the given alphabet.

INPUT:

- `alphabet` – an iterable

OUTPUT:

WordMorphism

EXAMPLES:

```
sage: m = WordMorphism('a->b,b->a')
sage: m.restrict_domain('a')
WordMorphism: a->b
sage: m.restrict_domain('')
WordMorphism:
sage: m.restrict_domain('A')
WordMorphism:
```

(continues on next page)

(continued from previous page)

```
sage: m.restrict_domain('Aa')
WordMorphism: a->b
```

The input alphabet must be iterable:

```
sage: m.restrict_domain(66)
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

reversal()

Return the reversal of `self`.

EXAMPLES:

```
sage: WordMorphism('6->ab,y->5,0->asd').reversal()
WordMorphism: 0->dsa, 6->ba, y->5
sage: WordMorphism('a->ab,b->a').reversal()
WordMorphism: a->ba, b->a
```

simplify_alphabet_size(*Z=None*)

If this morphism is simplifiable, return morphisms h and k such that this morphism is simplifiable with respect to h and k, otherwise raise `ValueError`.

This method is quite fast if this morphism is non-injective, but very slow if it is injective.

Let $f : X^* \to Y^*$ be a morphism. Then f is simplifiable with respect to morphisms $h : X^* \to Z^*$ and $k : Z^* \to Y^*$, if $f = k \circ h$ and $|Z| < |X|$. If also $Y \subseteq X$, then the morphism $g : Z^* \to Z^* = h \circ k$ is a simplification of f (with respect to h and k).

Loosely speaking, a morphism is simplifiable if it contains "more letters than is needed". Non-injectivity implies simplifiability. Simplification preserves some properties of the original morphism (e.g. repetitiveness).

For more information see Section 3 in [KO2000].

INPUT:

- `Z` – iterable (default: `self.domain().alphabet()`), whose elements are used as an alphabet for the simplification.

EXAMPLES:

Example of a simplifiable (non-injective) morphism:

```
sage: f = WordMorphism('a->aca,b->badc,c->acab,d->adc')
sage: h, k = f.simplify_alphabet_size('xyz'); h, k
(WordMorphism: a->x, b->zy, c->xz, d->y, WordMorphism: x->aca, y->adc, z->b)
sage: k * h == f
True
sage: g = h * k; g
WordMorphism: x->xxzx, y->xyxz, z->zy
```

Example of a simplifiable (injective) morphism:

```
sage: f = WordMorphism('a->abcc,b->abcd,c->abdc,d->abdd')
sage: h, k = f.simplify_alphabet_size('xyz'); h, k
(WordMorphism: a->xyy, b->xyz, c->xzy, d->xzz, WordMorphism: x->ab, y->c, z->
↪d)
sage: k * h == f
```

(continues on next page)

(continued from previous page)

```
True
sage: g = h * k; g
WordMorphism: x->xyyxyz, y->xzy, z->xzz
```

Example of a non-simplifiable morphism:

```
sage: WordMorphism('a->aa').simplify_alphabet_size()
Traceback (most recent call last):
...
ValueError: self (a->aa) is not simplifiable
```

Example of an erasing morphism:

```
sage: f = WordMorphism('a->abc,b->cc,c->')
sage: h, k = f.simplify_alphabet_size(); h, k
(WordMorphism: a->a, b->b, c->, WordMorphism: a->abc, b->cc)
sage: k * h == f
True
sage: g = h * k; g
WordMorphism: a->ab, b->
```

Example of a morphism, that is not an endomorphism:

```
sage: f = WordMorphism('a->xx,b->xy,c->yx,d->yy')
sage: h, k = f.simplify_alphabet_size(NN); h, k
(WordMorphism: a->00, b->01, c->10, d->11, WordMorphism: 0->x, 1->y)
sage: k * h == f
True
sage: len(k.domain().alphabet()) < len(f.domain().alphabet())
True
```

simplify_until_injective()

Return a quadruplet (g, h, k, i), where g is an injective simplification of this morphism with respect to h, k and i.

Requires this morphism to be an endomorphism.

This methods basically calls *simplify_alphabet_size()* until the returned simplification is injective. If this morphism is already injective, a quadruplet (g, h, k, i) is still returned, where g is this morphism, h and k are the identity morphisms and i is 0.

Let $f : X^* \to Y^*$ be a morphism and $Y \subseteq X$. Then $g : Z^* \to Z^*$ is an injective simplification of f with respect to morphisms $h : X^* \to Z^*$ and $k : Z^* \to Y^*$ and a positive integer i, if g is injective, $|Z| < |X|$, $g^i = h \circ k$ and $f^i = k \circ h$.

For more information see Section 4 in [KO2000].

EXAMPLES:

```
sage: f = WordMorphism('a->abc,b->a,c->bc')
sage: g, h, k, i = f.simplify_until_injective(); g, h, k, i
(WordMorphism: a->aa, WordMorphism: a->aa, b->a, c->a, WordMorphism: a->abc,␣
↪2)
sage: g.is_injective()
True
sage: g**i == h * k
True
```

(continues on next page)

(continued from previous page)

```
sage: f**i == k * h
True
```

sage.combinat.words.morphism.**get_cycles**(*f*, *domain*)

Return the list of cycles of the function `f` contained in `domain`.

INPUT:

- `f` – function.
- `domain` – iterable, a subdomain of the domain of definition of `f`.

EXAMPLES:

```
sage: from sage.combinat.words.morphism import get_cycles
sage: get_cycles(lambda i: (i+1)%3, [0,1,2])
[(0, 1, 2)]
sage: get_cycles(lambda i: [0,0,0][i], [0,1,2])
[(0,)]
sage: get_cycles(lambda i: [1,1,1][i], [0,1,2])
[(1,)]
sage: get_cycles(lambda i: [2,3,0][i], [0,1,2])
[(0, 2)]
sage: d = {'a': 'a', 'b': 'b'}
sage: get_cycles(d.__getitem__, 'ba')
[('b',), ('a',)]
```

5.1.362 Word paths

This module implements word paths, which is an application of Combinatorics on Words to Discrete Geometry. A word path is the representation of a word as a discrete path in a vector space using a one-to-one correspondence between the alphabet and a set of vectors called steps. Many problems surrounding 2d lattice polygons (such as questions of self-intersection, area, inertia moment, etc.) can be solved in linear time (linear in the length of the perimeter) using theory from Combinatorics on Words.

On the square grid, the encoding of a path using a four-letter alphabet (for East, North, West and South directions) is also known as the Freeman chain code [1,2] (see [3] for further reading).

AUTHORS:

- Arnaud Bergeron (2008) : Initial version, path on the square grid
- Sébastien Labbé (2009-01-14) : New classes and hierarchy, doc and functions.

EXAMPLES:

The combinatorial class of all paths defined over three given steps:

```
sage: P = WordPaths('abc', steps=[(1,2), (-3,4), (0,-3)]); P
Word Paths over 3 steps
```

This defines a one-to-one correspondence between alphabet and steps:

```
sage: d = P.letters_to_steps()
sage: sorted(d.items())
[('a', (1, 2)), ('b', (-3, 4)), ('c', (0, -3))]
```

Creation of a path from the combinatorial class P defined above:

```
sage: p = P('abaccba'); p
Path: abaccba
```

Many functions can be used on p: the coordinates of its trajectory, ask whether p is a closed path, plot it and many other:

```
sage: list(p.points())
[(0, 0), (1, 2), (-2, 6), (-1, 8), (-1, 5), (-1, 2), (-4, 6), (-3, 8)]
sage: p.is_closed()
False
sage: p.plot()                                                                #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

To obtain a list of all the available word path specific functions, use `help(p)`:

```
sage: help(p)
Help on FiniteWordPath_2d_str in module sage.combinat.words.paths object:
...
Methods inherited from FiniteWordPath_2d:
...
Methods inherited from FiniteWordPath_all:
...
```

Since p is a finite word, many functions from the word library are available:

```
sage: p.crochemore_factorization()
(a, b, a, c, c, ba)
sage: p.is_palindrome()
False
sage: p[:3]
Path: aba
sage: len(p)
7
```

P also herits many functions from Words:

```
sage: P = WordPaths('rs', steps=[(1,2), (-1,4)]); P
Word Paths over 2 steps
sage: P.alphabet()
{'r', 's'}
sage: list(P.iterate_by_length(3))
[Path: rrr,
 Path: rrs,
 Path: rsr,
 Path: rss,
 Path: srr,
 Path: srs,
 Path: ssr,
 Path: sss]
```

When the number of given steps is half the size of alphabet, the opposite of vectors are used:

```
sage: P = WordPaths('abcd', [(1,0), (0,1)])
sage: sorted(P.letters_to_steps().items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
```

Some built-in combinatorial classes of paths:

```
sage: P = WordPaths('abAB', steps='square_grid'); P
Word Paths on the square grid
```

```
sage: D = WordPaths('()', steps='dyck'); D
Finite Dyck paths
sage: d = D('()()()(())'); d
Path: ()()()(())
sage: d.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

```
sage: P = WordPaths('abcdef', steps='triangle_grid')
sage: p = P('babaddefadabcadefaadfafabacdefa')
sage: p.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

Vector steps may be in more than 2 dimensions:

```
sage: d = [(1,0,0), (0,1,0), (0,0,1)]
sage: P = WordPaths(alphabet='abc', steps=d); P
Word Paths over 3 steps
sage: p = P('abcabcabcabcaabacabcababcacbabacacabcaccbcac')
sage: p.plot()                                                              #␣
↪needs sage.plot
Graphics3d Object
```

```
sage: d = [(1,3,5,1), (-5,1,-6,0), (0,0,1,9), (4,2,-1,0)]
sage: P = WordPaths(alphabet='rstu', steps=d); P
Word Paths over 4 steps
sage: p = P('rtusuusususuturrsust'); p
Path: rtusuusususuturrsust
sage: p.end_point()
(5, 31, -26, 30)
```

```
sage: CubePaths = WordPaths('abcABC', steps='cube_grid'); CubePaths
Word Paths on the cube grid
sage: CubePaths('abcabaabcabAAAAA').plot()                                  #␣
↪needs sage.plot
Graphics3d Object
```

The input data may be a str, a list, a tuple, a callable or a finite iterator:

```
sage: P = WordPaths([0, 1, 2, 3])
sage: P([0,1,2,3,2,1,2,3,2])
Path: 012321232
sage: P((0,1,2,3,2,1,2,3,2))
Path: 012321232
sage: P(lambda n:n%4, length=10)
Path: 0123012301
sage: P(iter([0,3,2,1]), length='finite')
Path: 0321
```

class sage.combinat.words.paths.**FiniteWordPath_2d**

Bases: *FiniteWordPath_all*

animate()

Return an animation object illustrating the path growing step by step.

EXAMPLES:

```
sage: P = WordPaths('abAB')
sage: p = P('aaababbb')
sage: a = p.animate(); print(a)                                                #␣
↪needs sage.plot
Animation with 9 frames
sage: show(a)                          # long time, optional - imagemagick,␣
↪needs sage.plot
sage: show(a, delay=35, iterations=3)        # long time, optional -␣
↪imagemagick, needs sage.plot
```

```
sage: P = WordPaths('abcdef',steps='triangle')
sage: p =  P('abcdef')
sage: a = p.animate(); print(a)                                                #␣
↪needs sage.plot
Animation with 8 frames
sage: show(a)                          # long time, optional - imagemagick,␣
↪needs sage.plot
```

If the path is closed, the plain polygon is added at the end of the animation:

```
sage: P = WordPaths('abAB')
sage: p = P('ababAbABABaB')
sage: a = p.animate(); print(a)                                                #␣
↪needs sage.plot
Animation with 14 frames
sage: show(a)                          # long time, optional - imagemagick,␣
↪needs sage.plot
```

Another example illustrating a Fibonacci tile:

```
sage: w = words.fibonacci_tile(2)
sage: a = w.animate(); print(a)                                                #␣
↪needs sage.plot
Animation with 54 frames
sage: show(a)                          # long time, optional - imagemagick,␣
↪needs sage.plot
```

The first 4 Fibonacci tiles in an animation:

```
sage: # needs sage.plot
sage: a = words.fibonacci_tile(0).animate()
```

(continues on next page)

(continued from previous page)

```
sage: b = words.fibonacci_tile(1).animate()
sage: c = words.fibonacci_tile(2).animate()
sage: d = words.fibonacci_tile(3).animate()
sage: print(a*b*c*d)
Animation with 296 frames
sage: show(a*b*c*d)                  # long time, optional - imagemagick
```

Note: If ImageMagick is not installed, you will get an error message like this:

```
convert: not found

Error: ImageMagick does not appear to be installed. Saving an
animation to a GIF file or displaying an animation requires
ImageMagick, so please install it and try again.
```

See www.imagemagick.org, for example.

---

area()

Return the area of a closed path.

INPUT:

- `self` – a closed path

EXAMPLES:

```
sage: P = WordPaths('abcd',steps=[(1,1),(-1,1),(-1,-1),(1,-1)])
sage: p = P('abcd')
sage: p.area()          #todo: not implemented
2
```

height()

Return the height of `self`.

The height of a $2d$-path is merely the difference between the highest and the lowest y-coordinate of each points traced by it.

OUTPUT:

non negative real number

EXAMPLES:

```
sage: Freeman = WordPaths('abAB')
sage: Freeman('aababaabbbAA').height()
5
```

The function is well-defined if self is not simple or close:

```
sage: Freeman('aabAAB').height()
1
sage: Freeman('abbABa').height()
2
```

This works for any $2d$-paths:

```
sage: Paths = WordPaths('ab', steps=[(1,0),(1,1)])
sage: p = Paths('abbaa')
sage: p.height()
2
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.height()
2
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.height()
2.59807621135332
```

height_vector()

Return the height at each point.

EXAMPLES:

```
sage: Paths = WordPaths('ab', steps=[(1,0),(0,1)])
sage: p = Paths('abbba')
sage: p.height_vector()
[0, 0, 1, 2, 3, 3]
```

plot(*pathoptions={'rgbcolor': 'red', 'thickness': 3}*, *fill=True*, *filloptions={'rgbcolor': 'red', 'alpha': 0.2}*, *startpoint=True*, *startoptions={'rgbcolor': 'red', 'pointsize': 100}*, *endarrow=True*, *arrowoptions={'rgbcolor': 'red', 'arrowsize': 20, 'width': 3}*, *gridlines=False*, *gridoptions={}*)

Return a 2d Graphics illustrating the path.

INPUT:

- `pathoptions` – (dict, default:dict(rgbcolor='red',thickness=3)), options for the path drawing
- `fill` – (boolean, default: `True`), if fill is True and if the path is closed, the inside is colored
- `filloptions` – (dict, default:dict(rgbcolor='red',alpha=0.2)), options for the inside filling
- `startpoint` – (boolean, default: `True`), draw the start point?
- `startoptions` – (dict, default:dict(rgbcolor='red',pointsize=100)) options for the start point drawing
- `endarrow` – (boolean, default: `True`), draw an arrow end at the end?
- `arrowoptions` – (dict, default:dict(rgbcolor='red',arrowsize=20, width=3)) options for the end point arrow
- `gridlines` – (boolean, default: `False`), show gridlines?
- `gridoptions` – (dict, default: {}), options for the gridlines

EXAMPLES:

A non closed path on the square grid:

```
sage: P = WordPaths('abAB')
sage: P('abababAABAB').plot()                                                  #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

A closed path on the square grid:

```
sage: P('abababAABABB').plot()                                                  #␣
↪needs sage.plot
Graphics object consisting of 4 graphics primitives
```

A Dyck path:

```
sage: P = WordPaths('()', steps='dyck')
sage: P('()()()((()))').plot()                                                  #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

A path in the triangle grid:

```
sage: P = WordPaths('abcdef', steps='triangle_grid')
sage: P('abcdedededefab').plot()                                                #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

A polygon of length 220 that tiles the plane in two ways:

```
sage: P = WordPaths('abAB')
sage: P(
↪'aBababAbababaBaBABaBababaBaBABAbABABaBababaBaBABaBababaBaBABaBababaBaBABAbABABaBABAbAbabAbABA
↪').plot()  # needs sage.plot
Graphics object consisting of 4 graphics primitives
```

With gridlines:

```
sage: P('abababababab').plot(gridlines=True)                                    #␣
↪needs sage.plot
```

plot_directive_vector(*options={'rgbcolor': 'blue'}*)

Return an arrow 2d graphics that goes from the start of the path to the end.

INPUT:

- `options` – dictionary, default: {'rgbcolor': 'blue'} graphic options for the arrow

If the start is the same as the end, a single point is returned.

EXAMPLES:

```
sage: P = WordPaths('abcd'); P
Word Paths on the square grid
sage: p = P('aaaccaccacacacaccccccbbdd'); p
Path: aaaccaccacacacaccccccbbdd
sage: R = p.plot() + p.plot_directive_vector()                                  #␣
↪needs sage.plot
sage: R.axes(False)                                                             #␣
↪needs sage.plot
sage: R.set_aspect_ratio(1)                                                     #␣
↪needs sage.plot
sage: R.plot()                                                                  #␣
↪needs sage.plot
Graphics object consisting of 4 graphics primitives
```

width()

Return the width of `self`.

The height of a $2d$-path is merely the difference between the rightmost and the leftmost x-coordinate of each points traced by it.

OUTPUT:

non negative real number

EXAMPLES:

```
sage: Freeman = WordPaths('abAB')
sage: Freeman('aababaabbbAA').width()
5
```

The function is well-defined if self is not simple or close:

```
sage: Freeman('aabAAB').width()
2
sage: Freeman('abbABa').width()
1
```

This works for any $2d$-paths:

```
sage: Paths = WordPaths('ab', steps=[(1,0),(1,1)])
sage: p = Paths('abbaa')
sage: p.width()
5
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.width()
6
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.width()
4.50000000000000
```

width_vector()

Return the width at each point.

EXAMPLES:

```
sage: Paths = WordPaths('ab', steps=[(1,0),(0,1)])
sage: p = Paths('abbba')
sage: p.width_vector()
[0, 1, 1, 1, 1, 2]
```

xmax()

Return the maximum of the x-coordinates of the path.

EXAMPLES:

```
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.xmax()
3
```

This works for any $2d$-paths:

```
sage: Paths = WordPaths('ab', steps=[(1,-1),(-1,1)])
sage: p = Paths('ababa')
sage: p.xmax()
```

(continues on next page)

(continued from previous page)

```
1
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.xmax()
6
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmax()
4.500000000000000
```

xmin()

Return the minimum of the x-coordinates of the path.

EXAMPLES:

```
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.xmin()
0
```

This works for any $2d$-paths:

```
sage: Paths = WordPaths('ab', steps=[(1,0),(-1,1)])
sage: p = Paths('abbba')
sage: p.xmin()
-2
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.xmin()
0
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmin()
0.000000000000000
```

ymax()

Return the maximum of the y-coordinates of the path.

EXAMPLES:

```
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.ymax()
3
```

This works for any $2d$-paths:

```
sage: Paths = WordPaths('ab', steps=[(1,-1),(-1,1)])
sage: p = Paths('ababa')
sage: p.ymax()
0
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.ymax()
2
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymax()
2.598076211353332
```

ymin()

Return the minimum of the y-coordinates of the path.

EXAMPLES:

```
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.ymin()
0
```

This works for any $2d$-paths:

```
sage: Paths = WordPaths('ab', steps=[(1,-1),(-1,1)])
sage: p = Paths('ababa')
sage: p.ymin()
-1
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.ymin()
0
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymin()
0.000000000000000
```

Bases: *FiniteWordPath_all*

plot(*pathoptions={'rgbcolor': 'red', 'arrow_head': True, 'thickness': 3}*, *startpoint=True*, *startoptions={'rgbcolor': 'red', 'size': 10}*)

INPUT:

- pathoptions – (dict, default:dict(rgbcolor='red',arrow_head=True, thickness=3)), options for the path drawing

- `startpoint` – (boolean, default: `True`), draw the start point?
- **`startoptions` – (dict, default:dict(rgbcolor='red',size=10))**
  options for the start point drawing

EXAMPLES:

```
sage: d = ( vector((1,3,2)), vector((2,-4,5)) )
sage: P = WordPaths(alphabet='ab', steps=d); P
Word Paths over 2 steps
sage: p = P('abababb'); p
Path: abababb
sage: p.plot()                                                              #␣

Bases: *WordDatatype_tuple*, *FiniteWordPath_3d*, *FiniteWord_class*

class sage.combinat.words.paths.**FiniteWordPath_all**

Bases: SageObject

directive_vector()

Return the directive vector of `self`.

The directive vector is the vector starting at the start point and ending at the end point of the path `self`.

EXAMPLES:

```
sage: WordPaths('abcdef')('abababab').directive_vector()
(6, 2*sqrt3)
sage: WordPaths('abAB')('abababab').directive_vector()
(4, 4)
sage: P = WordPaths('abcABC', steps='cube_grid')
sage: P('abababCC').directive_vector()
(4, 4, -2)
sage: WordPaths('abcdef')('abcdef').directive_vector()
(0, 0)
sage: P = WordPaths('abc', steps=[(1,3,7,9),(-4,1,0,0),(0,32,1,8)])
sage: P('abcabababacaacccbbcac').directive_vector()
(-16, 254, 63, 128)
```

end_point()

Return the end point of the path.

EXAMPLES:

```
sage: WordPaths('abcdef')('abababab').end_point()
(6, 2*sqrt3)
sage: WordPaths('abAB')('abababab').end_point()
(4, 4)
sage: P = WordPaths('abcABC', steps='cube_grid')
sage: P('abababCC').end_point()
(4, 4, -2)
sage: WordPaths('abcdef')('abcdef').end_point()
(0, 0)
sage: P = WordPaths('abc', steps=[(1,3,7,9),(-4,1,0,0),(0,32,1,8)])
sage: P('abcabababacaacccbbcac').end_point()
(-16, 254, 63, 128)
```

is_closed()

Return `True` if the path is closed.

A path is closed if the origin and the end of the path are equal.

EXAMPLES:

```
sage: P = WordPaths('abcd', steps=[(1,0),(0,1),(-1,0),(0,-1)])
sage: P('abcd').is_closed()
True
sage: P('abc').is_closed()
False
sage: P().is_closed()
True
sage: P('aacacc').is_closed()
True
```

is_simple()

Return `True` if the path is simple.

A path is simple if all its points are distinct.

If the path is closed, the last point is not considered.

EXAMPLES:

```
sage: P = WordPaths('abcdef',steps='triangle_grid');P
Word Paths on the triangle grid
sage: P('abc').is_simple()
True
sage: P('abcde').is_simple()
True
sage: P('abcdef').is_simple()
True
sage: P('ad').is_simple()
True
sage: P('aabdee').is_simple()
False
```

is_tangent()

The is_tangent() method, which is implemented for words, has an extended meaning for word paths, which is not implemented yet.

AUTHOR:

- Thierry Monteil

plot_projection(*v=None*, *letters=None*, *color=None*, *ring=None*, *size=12*, *kind='right'*)

Return an image of the projection of the successive points of the path into the space orthogonal to the given vector.

INPUT:

- `self` – a word path in a 3 or 4 dimension vector space
- `v` – vector (default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
- `letters` – iterable (default: None) of the letters to be projected. If None, then all the letters are considered.
- `color` – dictionary (default: None) of the letters mapped to colors. If None, automatic colors are chosen.
- `ring` – ring (default: None) where to do the computations. If None, RealField(53) is used.
- `size` – number (default: `12`) size of the points.
- `kind` – string (default: `'right'`) either `'right'` or `'left'`. The color of a letter is given to the projected prefix to the right or the left of the letter.

OUTPUT:

2d or 3d Graphic object.

EXAMPLES:

The Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('123',[(1,0,0),(0,1,0),(0,0,1)])
sage: w = P(D[:200])
sage: w.plot_projection(v)  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

In this case, the abelianized vector doesn't give a good projection:

```
sage: w.plot_projection()  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can project only the letters you want:

```
sage: w.plot_projection(v, letters='12')  # long time (2s)
Graphics object consisting of 168 graphics primitives
```

You can increase or decrease the precision of the computations by changing the ring of the projection matrix:

```
sage: w.plot_projection(v, ring=RealField(20))  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can change the size of the points:

```
sage: w.plot_projection(v, size=30)  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can assign the color of a letter to the projected prefix to the right or the left of the letter:

```
sage: w.plot_projection(v, kind='left')  # long time (2s)
Graphics object consisting of 200 graphics primitives
```

To remove the axis, do like this:

```
sage: r = w.plot_projection(v)                                                  #␣
↪needs sage.plot
sage: r.axes(False)                                                             #␣
↪needs sage.plot
sage: r                                 # long time (2s)                        #␣
↪needs sage.plot
Graphics object consisting of 200 graphics primitives
```

You can assign different colors to each letter:

```
sage: color = {'1': 'purple', '2': (.2,.3,.4), '3': 'magenta'}
sage: w.plot_projection(v, color=color)     # long time (2s)                    #␣
↪needs sage.plot
Graphics object consisting of 200 graphics primitives
```

The 3d-Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->14,4->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('1234',[(1,0,0,0), (0,1,0,0), (0,0,1,0), (0,0,0,1)])
sage: w = P(D[:200])
sage: w.plot_projection(v)                                                      #␣
↪needs sage.plot
Graphics3d Object
```

The dimension of vector space of the parent must be 3 or 4:

```
sage: P = WordPaths('ab', [(1, 0), (0, 1)])
sage: p = P('aabbabbab')
sage: p.plot_projection()                                                       #␣
↪needs sage.plot
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
TypeError: The dimension of the vector space (=2) must be 3 or 4
```

points (*include_last=True*)

Return an iterator yielding a list of points used to draw the path represented by this word.

INPUT:

- `include_last` – bool (default: `True`) whether to include the last point

EXAMPLES:

A simple closed square:

```
sage: P = WordPaths('abAB')
sage: list(P('abAB').points())
[(0, 0), (1, 0), (1, 1), (0, 1), (0, 0)]
```

A simple closed square without the last point:

```
sage: list(P('abAB').points(include_last=False))
[(0, 0), (1, 0), (1, 1), (0, 1)]
```

```
sage: list(P('abaB').points())
[(0, 0), (1, 0), (1, 1), (2, 1), (2, 0)]
```

projected_path (*v=None*, *ring=None*)

Return the path projected into the space orthogonal to the given vector.

INPUT:

- `v` – vector (default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
- `ring` – ring (default: None) where to do the computations. If None, RealField(53) is used.

OUTPUT:

word path

EXAMPLES:

The projected path of the tribonacci word:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('123',[(1,0,0),(0,1,0),(0,0,1)])
sage: w = P(D[:1000])
sage: p = w.projected_path(v)
sage: p
Path: 12131211213121213121112131213121121312121...
sage: p[:20].plot()                                                          #␣
↪needs sage.plot
Graphics object consisting of 3 graphics primitives
```

The `ring` argument allows to change the precision of the projected steps:

```
sage: p = w.projected_path(v, RealField(10))
sage: p
Path: 12131211213121213121121312132131211213121 21...
sage: p.parent().letters_to_steps()
{'1': (-0.53, 0.00), '2': (0.75, -0.48), '3': (0.41, 0.88)}
```

projected_point_iterator(*v=None*, *ring=None*)

Return an iterator of the projection of the orbit points of the path into the space orthogonal to the given vector.

INPUT:

- `v` – vector (default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
- `ring` – ring (default: None) where to do the computations. If None, RealField(53) is used.

OUTPUT:

iterator of points

EXAMPLES:

Projected points of the Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('123',[(1,0,0),(0,1,0),(0,0,1)])
sage: w = P(D[:200])
sage: it = w.projected_point_iterator(v)
sage: for i in range(6): next(it)
(0.000000000000000, 0.000000000000000)
(-0.526233343362516, 0.000000000000000)
(0.220830337618112, -0.477656250512816)
(-0.305403005744404, -0.477656250512816)
(0.100767309386062, 0.400890564600664)
(-0.425466033976454, 0.400890564600664)
```

Projected points of a 2d path:

```
sage: P = WordPaths('ab','ne')
sage: p = P('aabbabbab')
sage: it = p.projected_point_iterator(ring=RealField(20))
sage: for i in range(8): next(it)
(0.00000)
(0.78087)
(1.5617)
(0.93704)
(0.31235)
(1.0932)
(0.46852)
(-0.15617)
```

start_point()

Return the starting point of `self`.

OUTPUT:

vector

EXAMPLES:

```
sage: WordPaths('abcdef')('abcdef').start_point()
(0, 0)
sage: WordPaths('abcdef', steps='cube_grid')('abcdef').start_point()
(0, 0, 0)
sage: P = WordPaths('ab', steps=[(1,0,0,0),(0,1,0,0)])
sage: P('abbba').start_point()
(0, 0, 0, 0)
```

tikz_trajectory()

Return the trajectory of `self` as a `tikz` string.

EXAMPLES:

```
sage: P = WordPaths('abcdef')
sage: p = P('abcde')
sage: p.tikz_trajectory()
'(0.000, 0.000) -- (1.00, 0.000) -- (1.50, 0.866) -- (1.00, 1.73) -- (0.000,␣
↪1.73) -- (-0.500, 0.866)'
```

class sage.combinat.words.paths.**FiniteWordPath_all_callable**(*parent*, *callable*, *length=None*)

class sage.combinat.words.paths.**FiniteWordPath_hexagonal_grid**(*parent*, **args*, ***kwds*)

Bases: *FiniteWordPath_triangle_grid*

INPUT:

- `parent` – a parent object inheriting from Words_all that has the alphabet attribute defined
- `*args`, `**kwds` – arguments accepted by AbstractWord

EXAMPLES:

```
sage: F = WordPaths('abcdef', steps='hexagon'); F
Word Paths on the hexagonal grid
sage: f = F('aaabbbccddef'); f
Path: aaabbbccddef
```

```
sage: f == loads(dumps(f))
True
```

Bases: *WordDatatype_list*, *FiniteWordPath_north_east*, *FiniteWord_class*

class sage.combinat.words.paths.**FiniteWordPath_north_east_str**

Bases: *WordDatatype_str*, *FiniteWordPath_north_east*, *FiniteWord_class*

class sage.combinat.words.paths.**FiniteWordPath_north_east_tuple**

Bases: *WordDatatype_tuple*, *FiniteWordPath_north_east*, *FiniteWord_class*

class sage.combinat.words.paths.**FiniteWordPath_square_grid**

Bases: *FiniteWordPath_2d*

area()

Return the area of a closed path.

INPUT:

- `self` – a closed path

EXAMPLES:

```
sage: P = WordPaths('abAB', steps='square_grid')
sage: P('abAB').area()
1
sage: P('aabbAABB').area()
4
sage: P('aabbABAB').area()
3
```

The area of the Fibonacci tiles:

```
sage: [words.fibonacci_tile(i).area() for i in range(6)]
[1, 5, 29, 169, 985, 5741]
sage: [words.dual_fibonacci_tile(i).area() for i in range(6)]
[1, 5, 29, 169, 985, 5741]
sage: oeis(_)[0]                              # optional -- internet
A001653: Numbers k such that 2*k^2 - 1 is a square.
sage: _.first_terms()                         # optional -- internet
(1,
 5,
 29,
 169,
 985,
```

 1746860020068409,
 10181446324101389,
 59341817924539925)
```

is_closed()

Return whether `self` represents a closed path.

EXAMPLES:

```
sage: P = WordPaths('abAB', steps='square_grid')
sage: P('aA').is_closed()
True
sage: P('abAB').is_closed()
True
sage: P('ababAABB').is_closed()
True
sage: P('aaabbbAABB').is_closed()
False
sage: P('ab').is_closed()
False
```

is_simple()

Return whether the path is simple.

A path is simple if all its points are distinct.

If the path is closed, the last point is not considered.

Note: The linear algorithm described in the thesis of Xavier Provençal should be implemented here.

EXAMPLES:

```
sage: P = WordPaths('abAB', steps='square_grid')
sage: P('abab').is_simple()
True
sage: P('abAB').is_simple()
True
sage: P('abA').is_simple()
True
sage: P('aabABB').is_simple()
False
```

(continues on next page)

(continued from previous page)

```
sage: P().is_simple()
True
sage: P('A').is_simple()
True
sage: P('aA').is_simple()
True
sage: P('aaA').is_simple()
False
```

tikz_trajectory()

Return the trajectory of `self` as a `tikz` string.

EXAMPLES:

```
sage: f = words.fibonacci_tile(1)
sage: f.tikz_trajectory()
'(0, 0) -- (0, -1) -- (-1, -1) -- (-1, -2) -- (0, -2) -- (0, -3) -- (1, -3) --
↪ (1, -2) -- (2, -2) -- (2, -1) -- (1, -1) -- (1, 0) -- (0, 0)'
```

Bases: *WordDatatype_tuple*, *FiniteWordPath_square_grid*, *FiniteWord_class*

class sage.combinat.words.paths.**FiniteWordPath_triangle_grid**

Bases: *FiniteWordPath_2d*

xmax()

Return the maximum of the x-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmax()
4.50000000000000
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.xmax()
4.00000000000000
```

xmin()

Return the minimum of the x-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmin()
0.000000000000000
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.xmin()
-3.00000000000000
```

ymax()

Return the maximum of the y-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymax()
2.59807621135332
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.ymax()
8.66025403784439
```

ymin()

Return the minimum of the y-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymin()
0.000000000000000
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.ymin()
-0.866025403784439
```

class sage.combinat.words.paths.**FiniteWordPath_triangle_grid_callable**(*parent*, *callable*, *length=None*)

class sage.combinat.words.paths.**FiniteWordPath_triangle_grid_str**

Bases: *WordDatatype_str*, *FiniteWordPath_triangle_grid*, *FiniteWord_class*

class sage.combinat.words.paths.**FiniteWordPath_triangle_grid_tuple**

Bases: *WordDatatype_tuple*, *FiniteWordPath_triangle_grid*, *FiniteWord_class*

sage.combinat.words.paths.**WordPaths**(*alphabet*, *steps=None*)

Return the combinatorial class of paths of the given type of steps.

INPUT:

- `alphabet` – ordered alphabet
- `steps` – (default is `None`). It can be one of the following:
  - an iterable ordered container of as many vectors as there are letters in the alphabet. The vectors are associated to the letters according to their order in steps. The vectors can be a tuple or anything that can be passed to vector function.
  - an iterable ordered container of k vectors where k is half the size of alphabet. The vectors and their opposites are associated to the letters according to their order in steps (given vectors first, opposite vectors after).
  - `None`: In this case, the type of steps are guessed from the length of alphabet.
  - 'square_grid' or 'square': (default when size of alphabet is 4) The order is : East, North, West, South.
  - 'triangle_grid' or 'triangle':
  - 'hexagonal_grid' or 'hexagon': (default when size of alphabet is 6)
  - 'cube_grid' or 'cube':
  - 'north_east', 'ne' or 'NE': (the default when size of alphabet is 2)
  - 'dyck':

OUTPUT:

The combinatorial class of all paths of the given type.

EXAMPLES:

The steps can be given explicitly:

```
sage: WordPaths('abc', steps=[(1,2), (-1,4), (0,-3)])
Word Paths over 3 steps
```

Different type of input alphabet:

```
sage: WordPaths(range(3), steps=[(1,2), (-1,4), (0,-3)])
Word Paths over 3 steps
sage: WordPaths(['cric','crac','croc'], steps=[(1,2), (1,4), (0,3)])
Word Paths over 3 steps
```

Directions can be in three dimensions as well:

```
sage: WordPaths('ab', steps=[(1,2,2),(-1,4,2)])
Word Paths over 2 steps
```

When the number of given steps is half the size of alphabet, the opposite of vectors are used:

```
sage: P = WordPaths('abcd', [(1,0), (0,1)])
sage: P
Word Paths over 4 steps
sage: sorted(P.letters_to_steps().items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
```

When no steps are given, default classes are returned:

```
sage: WordPaths('ab')
Word Paths in North and East steps
sage: WordPaths(range(4))
Word Paths on the square grid
sage: WordPaths(range(6))
Word Paths on the hexagonal grid
```

There are many type of built-in steps…

On a two letters alphabet:

```
sage: WordPaths('ab', steps='north_east')
Word Paths in North and East steps
sage: WordPaths('()', steps='dyck')
Finite Dyck paths
```

On a four letters alphabet:

```
sage: WordPaths('ruld', steps='square_grid')
Word Paths on the square grid
```

On a six letters alphabet:

```
sage: WordPaths('abcdef', steps='hexagonal_grid')
Word Paths on the hexagonal grid
sage: WordPaths('abcdef', steps='triangle_grid')
Word Paths on the triangle grid
sage: WordPaths('abcdef', steps='cube_grid')
Word Paths on the cube grid
```

class sage.combinat.words.paths.**WordPaths_all**(*alphabet*, *steps*)

Bases: *FiniteWords*

The combinatorial class of all paths, i.e of all words over an alphabet where each letter is mapped to a step (a vector).

letters_to_steps()

Return the dictionary mapping letters to vectors (steps).

EXAMPLES:

```
sage: d = WordPaths('ab').letters_to_steps()
sage: sorted(d.items())
[('a', (0, 1)), ('b', (1, 0))]
sage: d = WordPaths('abcd').letters_to_steps()
sage: sorted(d.items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
sage: d = WordPaths('abcdef').letters_to_steps()
sage: sorted(d.items())
[('a', (1, 0)),
 ('b', (1/2, 1/2*sqrt3)),
 ('c', (-1/2, 1/2*sqrt3)),
 ('d', (-1, 0)),
 ('e', (-1/2, -1/2*sqrt3)),
 ('f', (1/2, -1/2*sqrt3))]
```

vector_space()

Return the vector space over which the steps of the paths are defined.

EXAMPLES:

```
sage: WordPaths('ab',steps='dyck').vector_space()
Ambient free module of rank 2 over the principal ideal domain Integer Ring
sage: WordPaths('ab',steps='north_east').vector_space()
Ambient free module of rank 2 over the principal ideal domain Integer Ring
sage: WordPaths('abcd',steps='square_grid').vector_space()
Ambient free module of rank 2 over the principal ideal domain Integer Ring
sage: WordPaths('abcdef',steps='hexagonal_grid').vector_space()
Vector space of dimension 2 over Number Field in sqrt3 with defining␣
↪polynomial x^2 - 3 with sqrt3 = 1.732050807568878?
sage: WordPaths('abcdef',steps='cube_grid').vector_space()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
sage: WordPaths('abcdef',steps='triangle_grid').vector_space()
Vector space of dimension 2 over Number Field in sqrt3 with defining␣
↪polynomial x^2 - 3 with sqrt3 = 1.732050807568878?
```

class sage.combinat.words.paths.**WordPaths_cube_grid**(*alphabet*)

Bases: *WordPaths_all*

The combinatorial class of all paths on the cube grid.

class sage.combinat.words.paths.**WordPaths_dyck**(*alphabet*)

Bases: *WordPaths_all*

The combinatorial class of all Dyck paths.

class sage.combinat.words.paths.**WordPaths_hexagonal_grid**(*alphabet*)

Bases: *WordPaths_triangle_grid*

The combinatorial class of all paths on the hexagonal grid.

class sage.combinat.words.paths.**WordPaths_north_east**(*alphabet*)

Bases: *WordPaths_all*

The combinatorial class of all paths using North and East directions.

class sage.combinat.words.paths.**WordPaths_square_grid**(*alphabet*)

Bases: *WordPaths_all*

The combinatorial class of all paths on the square grid.

class sage.combinat.words.paths.**WordPaths_triangle_grid**(*alphabet*)

Bases: *WordPaths_all*

The combinatorial class of all paths on the triangle grid.

5.1.363 Shuffle product of words

See also:

The module *sage.combinat.shuffle* contains a more general implementation of shuffle product.

class sage.combinat.words.shuffle_product.**ShuffleProduct_shifted**(*w1*, *w2*, *check=True*)

Bases: *ShuffleProduct_w1w2*

Shifted shuffle product of `w1` with `w2`.

This is the shuffle product of `w1` with the word obtained by adding the length of `w1` to every letter of `w2`.

Note that this class is meant to be used for words; it misbehaves when `w1` is a permutation or composition.

INPUT:

- `check` – boolean (default `True`) whether to check that all words in the shuffle product belong to the correct parent

EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_shifted
sage: w, u = Word([1,2]), Word([3,4])
sage: S = ShuffleProduct_shifted(w,u)
sage: S == loads(dumps(S))
True
```

class sage.combinat.words.shuffle_product.**ShuffleProduct_w1w2**(*w1*, *w2*, *check=True*)

Bases: `Parent`, `UniqueRepresentation`

The shuffle product of the two words `w1` and `w2`.

If u and v are two words, then the *shuffle product* of u and v is a certain multiset of words defined as follows: Let a and b be the lengths of u and v, respectively. For every a-element subset I of $\{1, 2, \cdots, a+b\}$, let $w(I)$ be the length-$a+b$ word such that:

- for every $1 \leq k \leq a$, the i_k-th letter of $w(I)$ is the k-th letter of u, where i_k is the k-th smallest element of I;
- for every $1 \leq l \leq b$, the j_l-th letter of $w(I)$ is the l-th letter of v, where j_l is the l-th smallest element of $\{1, 2, \cdots, a+b\} \setminus I$.

The shuffle product of u and v is then the multiset of all $w(I)$ with I ranging over the a-element subsets of $\{1, 2, \cdots, a+b\}$.

INPUT:

- `check` – boolean (default `True`) whether to check that all words in the shuffle product belong to the correct parent

EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_w1w2
sage: W = Words([1,2,3,4])
sage: s = ShuffleProduct_w1w2(W([1,2]),W([3,4]))
sage: sorted(s)
[word: 1234, word: 1324, word: 1342, word: 3124,
 word: 3142, word: 3412]
sage: s == loads(dumps(s))
True
sage: TestSuite(s).run()

sage: s = ShuffleProduct_w1w2(W([1,4,3]),W([2]))
sage: sorted(s)
[word: 1243, word: 1423, word: 1432, word: 2143]

sage: s = ShuffleProduct_w1w2(W([1,4,3]),W([]))
sage: sorted(s)
[word: 143]
```

cardinality()

Return the number of words in the shuffle product of `w1` and `w2`.

This is understood as a multiset cardinality, not as a set cardinality; it does not count the distinct words only.

It is given by $\binom{l_1+l_2}{l_1}$, where l_1 is the length of `w1` and where l_2 is the length of `w2`.

EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_w1w2
sage: w, u = map(Words("abcd"), ["ab", "cd"])
sage: S = ShuffleProduct_w1w2(w,u)
sage: S.cardinality()
6

sage: w, u = map(Words("ab"), ["ab", "ab"])
sage: S = ShuffleProduct_w1w2(w,u)
sage: S.cardinality()
6
```

5.1.364 Suffix Tries and Suffix Trees

class sage.combinat.words.suffix_trees.**DecoratedSuffixTree**(w)

Bases: *ImplicitSuffixTree*

The decorated suffix tree of a word.

A *decorated suffix tree* of a word w is the suffix tree of w marked with the end point of all squares in the w.

The symbol `$` is appended to `w` to ensure that each final state is a leaf of the suffix tree.

INPUT:

- w – a finite word

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import DecoratedSuffixTree
sage: w = Word('0011001')
sage: DecoratedSuffixTree(w)
Decorated suffix tree of : 0011001$
sage: w = Word('0011001', '01')
sage: DecoratedSuffixTree(w)
Decorated suffix tree of : 0011001$
```

ALGORITHM:

When using 'pair' as output, the squares are retrieved in linear time. The algorithm is an implementation of the one proposed in [DS2004].

square_vocabulary(*output='pair'*)

Return the list of distinct squares of self.word.

Two types of outputs are available *pair* and *word*. The algorithm is only truly linear if *output* is set to *pair*. A pair is a tuple (i, l) that indicates the factor self.word()[i:i+l]. The option 'word' return word objects.

INPUT:

- output – (default: "pair") either "pair" or "word"

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import DecoratedSuffixTree
sage: w = Word('aabb')
sage: sorted(DecoratedSuffixTree(w).square_vocabulary())
[(0, 0), (0, 2), (2, 2)]
sage: w = Word('00110011010')
sage: sorted(DecoratedSuffixTree(w).square_vocabulary(output="word"))
[word: , word: 00, word: 00110011, word: 01100110, word: 1010, word: 11]
```

class sage.combinat.words.suffix_trees.**ImplicitSuffixTree**(*word*)

Bases: SageObject

Construct the implicit suffix tree of a word w.

The suffix tree of a word w is a compactification of the suffix trie for w. The compactification removes all nodes that have exactly one incoming edge and exactly one outgoing edge. It consists of two components: a tree and a word. Thus, instead of labelling the edges by factors of w, we can labelled them by indices of the occurrence of the factors in w.

The following is a straightforward implementation of Ukkonen's on-line algorithm for constructing the implicit suffix tree [Ukko1995]. It constructs the suffix tree for w[:i] from that of w[:i-1].

GENERAL IDEA. The suffix tree of w[:i+1] can be obtained from that of w[:i] by visiting each node corresponding to a suffix of w[:i] and modifying the tree by applying one of two rules (either append a new node to the tree, or split an edge into two). The "active state" is the node where the algorithm begins and the "suffix link" carries us to the next node that needs to be dealt with.

TREE. The tree is modelled as an automaton, which is stored as a dictionary of dictionaries: it is keyed by the nodes of the tree, and the corresponding dictionary is keyed by pairs (i, j) of integers representing the word w[i-1:j]. This makes it faster to look up a particular transition beginning at a specific node.

STATES/NODES. The states will always be -1, 0, 1, …, n. The state -1 is special and is only used for the purposes of the algorithm. All transitions map -1 to 0, so this information is not explicitly stored in the transition function.

EXPLICIT/IMPLICIT NODES. By definition, some of the nodes will not be states, but merely locations along an edge; these are called implicit nodes. A node r (implicit or explicit) is referenced as a pair (s,(k,p)) where s is an ancestor of r and w[k-1:p] is the word read by transitioning from s to r in the suffix trie. A reference pair is canonical if s is the closest ancestor of r.

SUFFIX LINK. The algorithm makes use of a map from (some) nodes to other nodes, called the suffix link. This is stored as a dictionary.

ACTIVE STATE. We store as ._active_state the active state of the tree, the state where the algorithm will begin when processing the next letter.

RUNNING TIME. The running time and storage space of the algorithm is linear in the length of the word w (whereas for a suffix tree it is quadratic).

REFERENCES:

- [Ukko1995]

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w); t
Implicit Suffix Tree of the word: cacao
sage: ababb = Words([0,1])([0,1,0,1,1])
sage: s = ImplicitSuffixTree(ababb); s
Implicit Suffix Tree of the word: 01011
```

LZ_decomposition()

Return a list of index of the beginning of the block of the Lempel-Ziv decomposition of `self.word`

The *Lempel-Ziv decomposition* is the factorisation $u_1...u_k$ of a word $w = x_1...x_n$ such that u_i is the longest prefix of $u_i...u_k$ that has an occurrence starting before u_i or a letter if this prefix is empty.

OUTPUT:

Return a list `iB` of index such that the blocks of the decomposition are `self.word()[iB[k]:iB[k+1]]`

EXAMPLES:

```
sage: w = Word('abababb')
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 2, 6, 7]
sage: w = Word('abaababacabba')
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 2, 3, 6, 8, 9, 11, 13]
sage: w = Word([0, 0, 0, 1, 1, 0, 1])
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 3, 4, 5, 7]
sage: w = Word('0000100101')
sage: T = w.suffix_tree()
sage: T.LZ_decomposition()
[0, 1, 4, 5, 9, 10]
```

active_state()

Return the active state of the suffix tree.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.active_state()
(0, (6, 6))
```

edge_iterator()

Return an iterator over the edges of the suffix tree.

The edge from u to v labelled by (i, j) is yielded as the tuple $(u, v, (i, j))$.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("aaaaa")).edge_iterator() )
[(0, 1, (0, None))]
sage: sorted( ImplicitSuffixTree(Word([0,1,0,1])).edge_iterator() )
[(0, 1, (0, None)), (0, 2, (1, None))]
sage: sorted( ImplicitSuffixTree(Word()).edge_iterator() )
[]
```

factor_iterator(*n=None*)

Generate distinct factors of `self`.

INPUT:

- `n` – an integer, or `None`.

OUTPUT:

- If `n` is an integer, returns an iterator over all distinct factors of length `n`. If `n` is `None`, returns an iterator generating all distinct factors.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator() )
[word: , word: a, word: ac, word: aca, word: acao, word: ao, word: c, word:␣
↪ca, word: cac, word: caca, word: cacao, word: cao, word: o]
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator(1) )
[word: a, word: c, word: o]
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator(2) )
[word: ac, word: ao, word: ca]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator() )
[word: , word: 0, word: 00, word: 000]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator(2) )
[word: 00]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator(0) )
[word: ]
sage: sorted( ImplicitSuffixTree(Word()).factor_iterator() )
[word: ]
sage: sorted( ImplicitSuffixTree(Word()).factor_iterator(2) )
[]
```

leftmost_covering_set()

Compute the leftmost covering set of square pairs in `self.word()`. Return a square as a pair `(i,l)` designating factor `self.word()[i:i+l]`.

A leftmost covering set is a set such that the leftmost occurrence (j, l) of a square in `self.word()` is covered by a pair (i, l) in the set for all types of squares. We say that (j, l) is covered by (i, l) if (i, l) (i+1,l), ldots, (j,l)` are all squares.

The set is returned in the form of a list `P` such that `P[i]` contains all the lengths of squares starting at `i` in the set. The lists `P[i]` are sorted in decreasing order.

The algorithm used is described in [DS2004].

EXAMPLES:

```
sage: w = Word('abaabaabbaaabaaba')
sage: T = w.suffix_tree()
sage: T.leftmost_covering_set()
[[6], [6], [2], [], [], [], [], [2], [], [], [6, 2], [], [], [], [], [], []]
sage: w = Word('abaca')
sage: T = w.suffix_tree()
sage: T.leftmost_covering_set()
[[], [], [], [], []]
sage: T = Word('aaaaa').suffix_tree()
sage: T.leftmost_covering_set()
[[4, 2], [], [], [], []]
```

number_of_factors(*n=None*)

Count the number of distinct factors of `self.word()`.

INPUT:

- `n` – an integer, or `None`.

OUTPUT:

- If `n` is an integer, returns the number of distinct factors of length `n`. If `n` is `None`, returns the total number of distinct factors.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: t = ImplicitSuffixTree(Word([1,2,1,3,1,2,1]))
sage: t.number_of_factors()
22
sage: t.number_of_factors(1)
3
sage: t.number_of_factors(9)
0
sage: t.number_of_factors(0)
1
```

```
sage: t = ImplicitSuffixTree(Word("cacao"))
sage: t.number_of_factors()
13
sage: list(map(t.number_of_factors, range(10)))
[1, 3, 3, 3, 2, 1, 0, 0, 0, 0]
```

```
sage: t = ImplicitSuffixTree(Word("c"*1000))
sage: t.number_of_factors()
1001
sage: t.number_of_factors(17)
1
```

(continues on next page)

(continued from previous page)

```
sage: t.number_of_factors(0)
1
```

```
sage: ImplicitSuffixTree(Word()).number_of_factors()
1
```

```
sage: blueberry = ImplicitSuffixTree(Word("blueberry"))
sage: blueberry.number_of_factors()
43
sage: list(map(blueberry.number_of_factors, range(10)))
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]
```

plot(*word_labels=False*, *layout='tree'*, *tree_root=0*, *tree_orientation='up'*, *vertex_colors=None*, *edge_labels=True*, **args*, ***kwds*)

Return a Graphics object corresponding to the transition graph of the suffix tree.

INPUT:

- `word_labels` – boolean (default: `False`) if `False`, labels the edges by pairs (i, j); if `True`, labels the edges by `word[i:j]`.
- `layout` – (default: `'tree'`)
- `tree_root` – (default: 0)
- `tree_orientation` – (default: `'up'`)
- `vertex_colors` – (default: `None`)
- `edge_labels` – (default: `True`)

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=True)              #␣
↪needs sage.graphs sage.plot
Graphics object consisting of 23 graphics primitives
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=False)             #␣
↪needs sage.graphs sage.plot
Graphics object consisting of 23 graphics primitives
```

process_letter(*letter*)

Modify the current implicit suffix tree producing the implicit suffix tree for `self.word() + letter`.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w[:-1]); t
Implicit Suffix Tree of the word: caca
sage: t.process_letter(w[-1]); t
Implicit Suffix Tree of the word: cacao
```

```
sage: W = Words([0,1])
sage: s = ImplicitSuffixTree(W([0,1,0,1])); s
Implicit Suffix Tree of the word: 0101
sage: s.process_letter(W([1])[0]); s
Implicit Suffix Tree of the word: 01011
```

show(*word_labels=None*, **args*, ***kwds*)

Display the output of *plot()*.

INPUT:

- word_labels – (default: None) if False, labels the edges by pairs (i, j); if True, labels the edges by word[i:j].

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("cao")("cacao")
sage: t = ImplicitSuffixTree(w)
sage: t.show(word_labels=True)                                              #␣
↪needs sage.plot
sage: t.show(word_labels=False)                                             #␣
↪needs sage.plot
```

states()

Return the states (explicit nodes) of the suffix tree.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.states()
[0, 1, 2, 3, 4, 5, 6, 7]
```

suffix_link(*state*)

Evaluate the suffix link map of the implicit suffix tree on state.

Note that the suffix link is not defined for all states.

The suffix link of a state x' that corresponds to the suffix x is defined to be -1 is x' is the root (0) and y' otherwise, where y' is the state corresponding to the suffix x[1:].

INPUT:

- state – a state

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.suffix_link(3)
5
sage: t.suffix_link(5)
0
sage: t.suffix_link(0)
-1
sage: t.suffix_link(-1)
Traceback (most recent call last):
    ...
TypeError: there is no suffix link from -1
```

suffix_walk(*edge*, *l*)

Return the state of "w" if the input state is "aw".

If the input state `(edge, l)` is path labeled "aw" with "a" a letter, the output is the state which is path labeled "w".

INPUT:

- `edge` – the edge containing the state
- `l` – the string-depth of the state on edge (`l`>0)

OUTPUT:

Return `("explicit", end_node)` if the state of w is an explicit state and `("implicit", edge, d)` is obtained by reading `d` letters on `edge`.

EXAMPLES:

```
sage: T = Word('00110111011').suffix_tree()
sage: T.suffix_walk((0, 5), 1)
('explicit', 0)
sage: T.suffix_walk((7, 3), 1)
('implicit', (9, 4), 1)
```

to_digraph(*word_labels=False*)

Return a `DiGraph` object of the transition graph of the suffix tree.

INPUT:

- `word_labels` – boolean (default: `False`) if `False`, labels the edges by pairs (i, j); if `True`, labels the edges by `word[i:j]`.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.to_digraph()                                                    #␣
↪needs sage.graphs
Digraph on 8 vertices
```

to_explicit_suffix_tree()

Convert `self` to an explicit suffix tree.

It is obtained by processing an end of string letter as if it were a regular letter, except that no new leaf nodes are created (thus, the only thing that happens is that some implicit nodes become explicit).

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w)
sage: t.to_explicit_suffix_tree()
```

```
sage: W = Words([0,1])
sage: s = ImplicitSuffixTree(W([0,1,0,1,1]))
sage: s.to_explicit_suffix_tree()
```

transition_function(*word*, *node=0*)

Return the node obtained by starting from `node` and following the edges labelled by the letters of `word`.

OUTPUT:

("explicit", end_node) if we end at end_node, or ("implicit", edge, d) if we end d spots along an edge.

INPUT:

- word – a word
- node – (default: 0) starting node

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.transition_function(W([0,1,0]))
('implicit', (3, 1), 1)
sage: t.transition_function(W([0,1,2]))
('explicit', 4)
sage: t.transition_function(W([0,1,2]), 5)
('explicit', 2)
sage: t.transition_function(W([0,1]), 5)
('implicit', (5, 2), 2)
```

transition_function_dictionary()

Return the transition function as a dictionary of dictionaries.

The format is consistent with the input format for DiGraph.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words("aco")
sage: t = ImplicitSuffixTree(W("cac"))
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}}
```

```
sage: W = Words([0,1])
sage: t = ImplicitSuffixTree(W([0,1,0]))
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}}
```

trie_type_dict()

Return a dictionary in a format compatible with that of the suffix trie transition function.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree,␣
↪SuffixTrie
sage: W = Words("ab")
sage: t = ImplicitSuffixTree(W("aba"))
sage: d = t.trie_type_dict()
sage: len(d)
5
sage: d                          # random
{(4, word: b): 5, (0, word: a): 4, (0, word: b): 3, (5, word: a): 1, (3,␣
↪word: a): 2}
```

uncompactify()

Return the tree obtained from self by splitting edges so that they are labelled by exactly one letter.

The resulting tree is isomorphic to the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree,␣
↪SuffixTrie
sage: abbab = Words("ab")("abbab")
sage: s = SuffixTrie(abbab)
sage: t = ImplicitSuffixTree(abbab)
sage: t.uncompactify().is_isomorphic(s.to_digraph())                    #␣
↪needs sage.graphs
True
```

word()

Return the word whose implicit suffix tree this is.

class sage.combinat.words.suffix_trees.**SuffixTrie**(*word*)

Bases: SageObject

Construct the suffix trie of the word w.

The suffix trie of a finite word w is a data structure representing the factors of w. It is a tree whose edges are labelled with letters of w, and whose leafs correspond to suffixes of w.

This is a straightforward implementation of Algorithm 1 from [Ukko1995]. It constructs the suffix trie of w[:i] from that of w[:i-1].

A suffix trie is modelled as a deterministic finite-state automaton together with the suffix_link map. The set of states corresponds to factors of the word (below we write x' for the state corresponding to x); these are always 0, 1, …. The state 0 is the initial state, and it corresponds to the empty word. For the purposes of the algorithm, there is also an auxiliary state -1. The transition function t is defined as:

```
t(-1,a) = 0 for all letters a; and
t(x',a) = y' for all x',y' \in Q such that y = xa,
```

and the suffix link function is defined as:

```
suffix_link(0) = -1;
suffix_link(x') = y', if x = ay for some letter a.
```

REFERENCES:

- [Ukko1995]

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w); t
Suffix Trie of the word: cacao
```

```
sage: e = Words("ab")()
sage: t = SuffixTrie(e); t
Suffix Trie of the word:
sage: t.process_letter("a"); t
Suffix Trie of the word: a
sage: t.process_letter("b"); t
Suffix Trie of the word: ab
sage: t.process_letter("a"); t
Suffix Trie of the word: aba
```

active_state()

Return the active state of the suffix trie.

This is the state corresponding to the word as a suffix of itself.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: t.active_state()
8
```

```
sage: u = Words([0,1])([0,1,1,0,1,0,0,1])
sage: s = SuffixTrie(u)
sage: s.active_state()
22
```

final_states()

Return the set of final states of the suffix trie.

These are the states corresponding to the suffixes of `self.word()`. They are obtained be repeatedly following the suffix link from the active state until we reach 0.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: t.final_states() == Set([8, 9, 10, 11, 12, 0])
True
```

has_suffix(*word*)

Return `True` if and only if `word` is a suffix of `self.word()`.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: [t.has_suffix(w[i:]) for i in range(w.length()+1)]
[True, True, True, True, True, True]
sage: [t.has_suffix(w[:i]) for i in range(w.length()+1)]
[True, False, False, False, False, True]
```

node_to_word(*state=0*)

Return the word obtained by reading the edge labels from 0 to `state`.

INPUT:

- `state` – (default: 0) a state

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("abc")("abcba")
sage: t = SuffixTrie(w)
sage: t.node_to_word(10)
word: abcba
```

(continues on next page)

(continued from previous page)

```
sage: t.node_to_word(7)
word: abcb
```

plot(*layout='tree'*, *tree_root=0*, *tree_orientation='up'*, *vertex_colors=None*, *edge_labels=True*, **args*, ***kwds*)

Return a Graphics object corresponding to the transition graph of the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: SuffixTrie(Word("cacao")).plot()                                          #␣
↪needs sage.plot
Graphics object consisting of 38 graphics primitives
```

process_letter(*letter*)

Modify `self` to produce the suffix trie for `self.word() + letter`.

Note: `letter` must occur within the alphabet of the word.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("ab")("ababba")
sage: t = SuffixTrie(w); t
Suffix Trie of the word: ababba
sage: t.process_letter("a"); t
Suffix Trie of the word: ababbaa
```

show(**args*, ***kwds*)

Display the output of *plot()*.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cac")
sage: t = SuffixTrie(w)
sage: t.show()                                                                  #␣
↪needs sage.plot
```

states()

Return the states of the automaton defined by the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words([0,1])([0,1,1])
sage: t = SuffixTrie(w)
sage: t.states()
[0, 1, 2, 3, 4]
```

```
sage: u = Words("aco")("cacao")
sage: s = SuffixTrie(u)
sage: s.states()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]
```

suffix_link(*state*)

Evaluate the suffix link map of the suffix trie on `state`.

Note that the suffix link map is not defined on -1.

INPUT:

- `state` – a state

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: list(map(t.suffix_link, range(13)))
[-1, 0, 3, 0, 5, 1, 7, 2, 9, 10, 11, 12, 0]
sage: t.suffix_link(0)
-1
```

to_digraph()

Return a `DiGraph` object of the transition graph of the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cac")
sage: t = SuffixTrie(w)
sage: d = t.to_digraph(); d                                                 #␣
↪needs sage.graphs
Digraph on 6 vertices
sage: d.adjacency_matrix()                                                  #␣
↪needs sage.graphs sage.modules
[0 1 0 1 0 0]
[0 0 1 0 0 0]
[0 0 0 0 1 0]
[0 0 0 0 0 1]
[0 0 0 0 0 0]
[0 0 0 0 0 0]
```

transition_function(*node*, *word*)

Return the state reached by beginning at `node` and following the arrows in the transition graph labelled by the letters of `word`.

INPUT:

- `node` – a node
- `word` – a word

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words([0,1])([0,1,0,1,1])
sage: t = SuffixTrie(w)
sage: all(t.transition_function(u, letter) == v
....:     for (u, letter), v in t._transition_function.items())
True
```

word()

Return the word whose suffix tree this is.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("abc")("abcba")
sage: t = SuffixTrie(w)
sage: t.word()
word: abcba
sage: t.word() == w
True
```

5.1.365 Word classes

AUTHORS:

- Arnaud Bergeron
- Amy Glen
- Sébastien Labbé
- Franco Saliola

class sage.combinat.words.word.**FiniteWord_callable**(*parent*, *callable*, *length=None*)

Bases: *WordDatatype_callable*, *FiniteWord_class*

Finite word represented by a callable.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: f = lambda n : 3 if n > 8 else 6
sage: w = Word(f, length=30, caching=False)
sage: w
word: 666666666333333333333333333333
sage: w.is_symmetric()
True
```

class sage.combinat.words.word.**FiniteWord_callable_with_caching**(*parent*, *callable*, *length=None*)

Bases: *WordDatatype_callable_with_caching*, *FiniteWord_class*

Finite word represented by a callable (with caching).

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: f = lambda n : n % 3
sage: w = Word(f, length=32)
sage: w
word: 01201201201201201201201201201201
sage: w.border()
word: 0120120120120120120120120120
```

class sage.combinat.words.word.**FiniteWord_char**

Bases: *WordDatatype_char*, *FiniteWord_class*

Finite word represented by an array `unsigned char *` (i.e. integers between 0 and 255).

For any word `w`, type `w.<TAB>` to see the functions that can be applied to `w`.

EXAMPLES:

```
sage: W = Words(range(20))

sage: w = W(list(range(1, 10)) * 2)
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_char'>
sage: w
word: 123456789123456789

sage: w.is_palindrome()
False
sage: (w*w[::-1]).is_palindrome()
True
sage: (w[:-1:]*w[::-1]).is_palindrome()
True

sage: w.is_lyndon()
False
sage: W(list(range(10)) + [10, 10]).is_lyndon()
True

sage: w.is_square_free()
False
sage: w[:-1].is_square_free()
True

sage: u = W([randint(0,10) for i in range(10)])
sage: (u*u).is_square()
True
sage: (u*u*u).is_cube()
True

sage: len(w.factor_set())
127
sage: w.rauzy_graph(5)                                                    #␣
↪needs sage.graphs
Looped digraph on 9 vertices

sage: u = W([1,2,3])
sage: w.first_occurrence(u)
0
sage: w.first_occurrence(u, start=1)
9
```

class sage.combinat.words.word.**FiniteWord_iter**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype_iter*, *FiniteWord_class*

Finite word represented by an iterator.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: w = Word(iter(range(10)), caching=False)
sage: w
word: 0123456789
```

(continues on next page)

(continued from previous page)

```
sage: w.finite_differences()
word: 111111111
```

class sage.combinat.words.word.**FiniteWord_iter_with_caching**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype_iter_with_caching*, *FiniteWord_class*

Finite word represented by an iterator (with caching).

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: w = Word(iter('abcdef'))
sage: w.conjugate(2)
word: cdefab
```

class sage.combinat.words.word.**FiniteWord_list**

Bases: *WordDatatype_list*, *FiniteWord_class*

Finite word represented by a Python list.

For any word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: w = Word(range(10))
sage: w.iterated_right_palindromic_closure()
word: 0102010301020104010201030102010501020103...
```

class sage.combinat.words.word.**FiniteWord_morphic**(*parent*, *morphism*, *letter*, *coding=None*, *length=+Infinity*)

Bases: WordDatatype_morphic, *FiniteWord_class*

Finite morphic word.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: m = WordMorphism("a->ab,b->")
sage: w = m.fixed_point("a")
sage: w
word: ab
```

class sage.combinat.words.word.**FiniteWord_str**

Bases: *WordDatatype_str*, *FiniteWord_class*

Finite word represented by a Python str.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: w = Word('abcdef')
sage: w.is_square()
False
```

class sage.combinat.words.word.**FiniteWord_tuple**

Bases: *WordDatatype_tuple*, *FiniteWord_class*

Finite word represented by a Python tuple.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

EXAMPLES:

```
sage: w = Word(())
sage: w.is_empty()
True
```

class sage.combinat.words.word.**InfiniteWord_callable**(*parent*, *callable*, *length=None*)

Bases: *WordDatatype_callable*, *InfiniteWord_class*

Infinite word represented by a callable.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

Infinite words behave like a Python list : they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```
sage: w = Word(lambda n:n, caching=False)
sage: w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,
↪28,29,30,31,32,33,34,35,36,37,38,39,...
sage: w.iterated_right_palindromic_closure()
word: 0102010301020104010201030102010501020103...
```

class sage.combinat.words.word.**InfiniteWord_callable_with_caching**(*parent*, *callable*, *length=None*)

Bases: *WordDatatype_callable_with_caching*, *InfiniteWord_class*

Infinite word represented by a callable (with caching).

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

Infinite words behave like a Python list : they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```
sage: w = Word(lambda n:n)
sage: factor = w[4:13]
sage: factor
word: 4,5,6,7,8,9,10,11,12
```

class sage.combinat.words.word.**InfiniteWord_iter**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype_iter*, *InfiniteWord_class*

Infinite word represented by an iterable.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

Infinite words behave like a Python list : they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```
sage: from itertools import chain, cycle
sage: w = Word(chain('letsgo', cycle('forever')), caching=False)
sage: w
word: letsgoforeverforeverforeverforeverforeve...
sage: prefix = w[:100]
sage: prefix
word: letsgoforeverforeverforeverforeverforeve...
sage: prefix.is_lyndon()
False
```

class sage.combinat.words.word.**InfiniteWord_iter_with_caching**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype_iter_with_caching*, *InfiniteWord_class*

Infinite word represented by an iterable (with caching).

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

Infinite words behave like a Python list : they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```
sage: from itertools import cycle
sage: w = Word(cycle([9,8,4]))
sage: w
word: 984984984984984984984984984984984984984...
sage: prefix = w[:23]
sage: prefix
word: 98498498498498498498498
sage: prefix.minimal_period()
3
```

class sage.combinat.words.word.**InfiniteWord_morphic**(*parent*, *morphism*, *letter*, *coding=None*, *length=+Infinity*)

Bases: WordDatatype_morphic, *InfiniteWord_class*

Morphic word of infinite length.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

Infinite words behave like a Python list : they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```
sage: m = WordMorphism('a->ab,b->a')
sage: w = m.fixed_point('a')
sage: w
word: abaababaabaababaababaabaababaabaababaaba...
```

sage.combinat.words.word.**Word**(*data=None*, *alphabet=None*, *length=None*, *datatype=None*, *caching=True*, *RSK_data=None*)

Construct a word.

INPUT:

- `data` – (default: `None`) list, string, tuple, iterator, free monoid element, `None` (shorthand for `[]`), or a callable defined on `[0,1,...,length]`.

- `alphabet` – any argument accepted by Words
- `length` – (default: `None`) This is dependent on the type of data. It is ignored for words defined by lists, strings, tuples, etc., because they have a naturally defined length. For callables, this defines the domain of definition, which is assumed to be `[0, 1, 2, ..., length-1]`. For iterators: Infinity if you know the iterator will not terminate (default); `"unknown"` if you do not know whether the iterator terminates; `"finite"` if you know that the iterator terminates, but do not know the length.
- `datatype` – (default: `None`) `None`, `"list"`, `"str"`, `"tuple"`, `"iter"`, `"callable"`. If `None`, then the function tries to guess this from the data.
- `caching` – (default: `True`) `True` or `False`. Whether to keep a cache of the letters computed by an iterator or callable.
- `RSK_data` – (Optional. Default: `None`) A semistandard and a standard Young tableau to run the inverse RSK bijection on.

Note: Be careful when defining words using callables and iterators. It appears that islice does not pickle correctly causing various errors when reloading. Also, most iterators do not support copying and should not support pickling by extension.

EXAMPLES:

Empty word:

```
sage: Word()
word:
```

Word with string:

```
sage: Word("abbabaab")
word: abbabaab
```

Word with string constructed from other types:

```
sage: Word([0,1,1,0,1,0,0,1], datatype="str")
word: 01101001
sage: Word((0,1,1,0,1,0,0,1), datatype="str")
word: 01101001
```

Word with list:

```
sage: Word([0,1,1,0,1,0,0,1])
word: 01101001
```

Word with list constructed from other types:

```
sage: Word("01101001", datatype="list")
word: 01101001
sage: Word((0,1,1,0,1,0,0,1), datatype="list")
word: 01101001
```

Word with tuple:

```
sage: Word((0,1,1,0,1,0,0,1))
word: 01101001
```

Word with tuple constructed from other types:

```
sage: Word([0,1,1,0,1,0,0,1], datatype="tuple")
word: 01101001
sage: Word("01101001", datatype="str")
word: 01101001
```

Word with iterator:

```
sage: from itertools import count
sage: Word(count())
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,
↪28,29,30,31,32,33,34,35,36,37,38,39,...
sage: Word(iter("abbabaab")) # iterators default to infinite words
word: abbabaab
sage: Word(iter("abbabaab"), length="unknown")
word: abbabaab
sage: Word(iter("abbabaab"), length="finite")
word: abbabaab
```

Word with function (a 'callable'):

```
sage: f = lambda n : add(Integer(n).digits(2)) % 2
sage: Word(f)
word: 01101001100101101001011001101001100100110...
sage: Word(f, length=8)
word: 01101001
```

Word over a string with a parent:

```
sage: w = Word("abbabaab", alphabet="abc"); w
word: abbabaab
sage: w.parent()
Finite words over {'a', 'b', 'c'}
```

Word from a free monoid element:

```
sage: M.<x,y,z> = FreeMonoid(3)
sage: Word(x^3*y*x*z^2*x)
word: xxxyxzzx
```

The default parent is the combinatorial class of all words:

```
sage: w = Word("abbabaab"); w
word: abbabaab
sage: w.parent()
Finite words over Set of Python objects of class 'object'
```

We can also input a semistandard tableau and a standard tableau to obtain a word from the inverse RSK algorithm using the `RSK_data` option:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: Word(RSK_data=[p, q])
word: 1322
```

class sage.combinat.words.word.**Word_iter**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype_iter*, *Word_class*

Word of unknown length (finite or infinite) represented by an iterable.

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

Words behave like a Python list : they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```
sage: w = Word(iter([1,1,4,9]*1000), length='unknown', caching=False)
sage: w
word: 11491149114911491149114911491149114911491149...
sage: w.delta()
word: 21121121121121121121121121121121121121121121...
```

class sage.combinat.words.word.**Word_iter_with_caching**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype_iter_with_caching*, *Word_class*

Word of unknown length (finite or infinite) represented by an iterable (with caching).

For such word w, type `w.` and hit `Tab` key to see the list of functions defined on w.

Words behave like a Python list : they can be sliced using square braquets to define for example a prefix or a factor.

EXAMPLES:

```
sage: w = Word(iter([1,2,3]*1000), length='unknown')
sage: w
word: 12312312312312312312312312312312312312312...
sage: w.finite_differences(mod=2)
word: 11011011011011011011011011011011011011011101...
```

5.1.366 Fast word datatype using an array of unsigned char

class sage.combinat.words.word_char.**WordDatatype_char**

Bases: *WordDatatype*

A Fast class for words represented by an array `unsigned char *`.

Currently, only handles letters in [0,255].

concatenate(*other*)

Concatenation of `self` and `other`.

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: W([0,2,1]).concatenate([0,0,0])
word: 021000
```

has_prefix(*other*)

Test whether `other` is a prefix of `self`.

INPUT:

- `other` – a word or a sequence (e.g. tuple, list)

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: w = W([0,1,1,0,1,2,0])
sage: w.has_prefix([0,1,1])
```

(continues on next page)

(continued from previous page)

```
True
sage: w.has_prefix([0,1,2])
False
sage: w.has_prefix(w)
True
sage: w.has_prefix(w[:-1])
True
sage: w.has_prefix(w[1:])
False
```

is_empty()

Return whether the word is empty.

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: W([0,1,2,2]).is_empty()
False
sage: W([]).is_empty()
True
```

is_square()

Return True if self is a square, and False otherwise.

EXAMPLES:

```
sage: w = Word([n % 4 for n in range(48)], alphabet=[0,1,2,3])
sage: w.is_square()
True
```

```
sage: w = Word([n % 4 for n in range(49)], alphabet=[0,1,2,3])
sage: w.is_square()
False
sage: (w*w).is_square()
True
```

length()

Return the length of the word as a Sage integer.

EXAMPLES:

```
sage: W = Words([0,1,2,3,4])
sage: w = W([0,1,2,0,3,2,1])
sage: w.length()
7
sage: type(w.length())
<class 'sage.rings.integer.Integer'>
sage: type(len(w))
<class 'int'>
```

letters()

Return the list of letters that appear in this word, listed in the order of first appearance.

EXAMPLES:

```
sage: W = Words(5)
sage: W([1,3,1,2,2,3,1]).letters()
[1, 3, 2]
```

longest_common_prefix(*other*)

Return the longest common prefix of this word and `other`.

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: W([0,1,0,2]).longest_common_prefix([0,1])
word: 01
sage: u = W([0,1,0,0,1])
sage: v = W([0,1,0,2])
sage: u.longest_common_prefix(v)
word: 010
sage: v.longest_common_prefix(u)
word: 010
```

Using infinite words is also possible (and the return type is also a of the same type as `self`):

```
sage: W([0,1,0,0]).longest_common_prefix(words.FibonacciWord())
word: 0100
sage: type(_)
<class 'sage.combinat.words.word.FiniteWord_char'>
```

An example of an intensive usage:

```
sage: W = Words([0,1])
sage: w = words.FibonacciWord()
sage: w = W(list(w[:5000]))
sage: L = [[len(w[n:].longest_common_prefix(w[n+fibonacci(i):])) for i in range(5,15)] for n in range(1,1000)]  # needs sage.libs.pari
sage: for n,l in enumerate(L):  # needs sage.libs.pari
....:     if l.count(0) > 4:
....:         print("{} {}".format(n+1,l))
375 [0, 13, 0, 34, 0, 89, 0, 233, 0, 233]
376 [0, 12, 0, 33, 0, 88, 0, 232, 0, 232]
608 [8, 0, 21, 0, 55, 0, 144, 0, 377, 0]
609 [7, 0, 20, 0, 54, 0, 143, 0, 376, 0]
985 [0, 13, 0, 34, 0, 89, 0, 233, 0, 610]
986 [0, 12, 0, 33, 0, 88, 0, 232, 0, 609]
```

longest_common_suffix(*other*)

Return the longest common suffix between this word and `other`.

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: W([0,1,0,2]).longest_common_suffix([2,0,2])
word: 02
sage: u = W([0,1,0,0,1])
sage: v = W([1,2,0,0,1])
sage: u.longest_common_suffix(v)
word: 001
```

(continues on next page)

(continued from previous page)

```
sage: v.longest_common_suffix(u)
word: 001
```

sage.combinat.words.word_char.**reversed_word_iterator**(*w*)

This function exists only because it is not possible to use yield in the special method __reversed__.

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: w = W([0,1,0,0,1,2])
sage: list(reversed(w)) # indirect doctest
[2, 1, 0, 0, 1, 0]
```

5.1.367 Datatypes for finite words

class sage.combinat.words.word_datatypes.**WordDatatype**

Bases: object

The generic WordDatatype class.

Any word datatype must contain two attributes (at least):

- _parent
- _hash

They are automatically defined here and it's not necessary (and forbidden) to define them anywhere else.

class sage.combinat.words.word_datatypes.**WordDatatype_list**

Bases: *WordDatatype*

Datatype class for words defined by lists.

length()

Return the length of the word.

EXAMPLES:

```
sage: w = Word([0,1,1,0])
sage: w.length()
4
```

number_of_letter_occurrences(*a*)

Returns the number of occurrences of the letter a in the word self.

INPUT:

- a – a letter

OUTPUT:

- integer

EXAMPLES:

```
sage: w = Word([0,1,1,0,1])
sage: w.number_of_letter_occurrences(0)
2
```

(continues on next page)

(continued from previous page)

```
sage: w.number_of_letter_occurrences(1)
3
sage: w.number_of_letter_occurrences(2)
0
```

See also:

sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()

class sage.combinat.words.word_datatypes.**WordDatatype_str**

Bases: *WordDatatype*

Datatype for words defined by strings.

find(*sub*, *start=0*, *end=None*)

Returns the index of the first occurrence of sub in self, such that sub is contained within self[start:end]. Returns -1 on failure.

INPUT:

- `sub` – string or word to search for.
- `start` – non negative integer (default: 0) specifying the position from which to start the search.
- `end` – non negative integer (default: None) specifying the position at which the search must stop. If None, then the search is performed up to the end of the string.

OUTPUT:

non negative integer or -1

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: w.find("a")
0
sage: w.find("a", 4)
5
sage: w.find("a", 4, 5)
-1
```

has_prefix(*other*)

Test whether `self` has `other` as a prefix.

INPUT:

- `other` – a word (an instance of `Word_class`) or a `str`.

OUTPUT:

- boolean

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: u = Word("abbab")
sage: w.has_prefix(u)
True
sage: u.has_prefix(w)
False
```

(continues on next page)

(continued from previous page)

```
sage: u.has_prefix("abbab")
True
```

has_suffix(*other*)

Test whether `self` has `other` as a suffix.

INPUT:

- `other` – a word (an instance of `Word_class`) or a `str`.

OUTPUT:

- boolean

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: u = Word("ababa")
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix("ababa")
True
```

is_prefix(*other*)

Test whether `self` is a prefix of `other`.

INPUT:

- `other` – a word (an instance of `Word_class`) or a `str`.

OUTPUT:

- boolean

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: u = Word("abbab")
sage: w.is_prefix(u)
False
sage: u.is_prefix(w)
True
sage: u.is_prefix("abbabaababababa")
True
```

is_suffix(*other*)

Test whether `self` is a suffix of `other`.

INPUT:

- `other` – a word (an instance of `Word_class`) or a `str`.

OUTPUT:

- boolean

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: u = Word("ababa")
sage: w.is_suffix(u)
False
sage: u.is_suffix(w)
True
sage: u.is_suffix("abbabaababababa")
True
```

length()

Return the length of the word.

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: w.length()
13
```

number_of_letter_occurrences(*letter*)

Count the number of occurrences of `letter`.

INPUT:

- `letter` – a letter

OUTPUT:

- integer

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: w.number_of_letter_occurrences('a')
7
sage: w.number_of_letter_occurrences('b')
6
sage: w.number_of_letter_occurrences('c')
0
```

```
sage: w.number_of_letter_occurrences('abb')
0
```

See also:

sage.combinat.words.finite_word.FiniteWord_class.number_of_factor_occurrences()

partition(*sep*)

Search for the separator sep in S, and return the part before it, the separator itself, and the part after it. The concatenation of the terms in the list gives back the initial word.

See also the split method.

Note: This just wraps Python's builtin `str::partition()` for `str`.

INPUT:

- `sep` – string or word

EXAMPLES:

```
sage: w = Word("MyTailorIsPoor")
sage: w.partition("Tailor")
[word: My, word: Tailor, word: IsPoor]
```

```
sage: w = Word("32303010303232123230323212101212321210 10")
sage: l = w.partition("323")
sage: print(l)
[word: , word: 323, word: 03010303232123230323212101212321210 10]
sage: sum(l, Word('')) == w
True
```

If the separator is not a string an error is raised:

```
sage: w = Word("le papa du papa du papa etait un petit pioupiou")
sage: w.partition(Word(['p','a','p','a']))
Traceback (most recent call last):
...
ValueError: the separator must be a string
```

rfind(*sub*, *start=0*, *end=None*)

Returns the index of the last occurrence of sub in self, such that sub is contained within self[start:end]. Returns -1 on failure.

INPUT:

- `sub` – string or word to search for.
- `start` – non negative integer (default: 0) specifying the position at which the search must stop.
- `end` – non negative integer (default: None) specifying the position from which to start the search. If None, then the search is performed up to the end of the string.

OUTPUT:

non negative integer or -1

EXAMPLES:

```
sage: w = Word("abbabaababababa")
sage: w.rfind("a")
12
sage: w.rfind("a", 4, 8)
6
sage: w.rfind("a", 4, 5)
-1
```

split(*sep=None*, *maxsplit=None*)

Returns a list of words, using sep as a delimiter string. If maxsplit is given, at most maxsplit splits are done.

See also the partition method.

Note: This just wraps Python's builtin `str::split()` for `str`.

INPUT:

- `sep` – string or word (default: None)
- `maxsplit` – positive integer (default: None)

OUTPUT:

- a list of words

EXAMPLES:

You can split along white space to find words in a sentence:

```
sage: w = Word("My tailor is poor")
sage: w.split(" ")
[word: My, word: tailor, word: is, word: poor]
```

The python behavior is kept when no argument is given:

```
sage: w.split()
[word: My, word: tailor, word: is, word: poor]
```

You can split in two words letters to get the length of blocks in the other letter:

```
sage: w = Word("ababbabaaba")
sage: w.split('a')
[word: , word: b, word: bb, word: b, word: , word: b, word: ]
sage: w.split('b')
[word: a, word: a, word: , word: a, word: aa, word: a]
```

You can split along words:

```
sage: w = Word("32303010303232123223032321")
sage: w.split("32")
[word: , word: 30301030, word: , word: 12, word: 30, word: , word: 1]
```

If the separator is not a string a `ValueError` is raised:

```
sage: w = Word("le papa du papa du papa etait un petit pioupiou")
sage: w.split(Word(['p','a','p','a']))
Traceback (most recent call last):
...
ValueError: the separator must be a string
```

class sage.combinat.words.word_datatypes.**WordDatatype_tuple**

Bases: *WordDatatype*

Datatype class for words defined by tuples.

length()

Return the length of the word.

EXAMPLES:

```
sage: w = Word((0,1,1,0))
sage: w.length()
4
```

5.1.368 Common words

AUTHORS:

- Franco Saliola (2008-12-17): merged into sage
- Sébastien Labbé (2008-12-17): merged into sage
- Arnaud Bergeron (2008-12-17): merged into sage
- Amy Glen (2008-12-17): merged into sage
- Sébastien Labbé (2009-12-19): Added S-adic words (Issue #7543)

USE:

To see a list of all word constructors, type `words.` and then press the `Tab` key. The documentation for each constructor includes information about each word, which provides a useful reference.

REFERENCES:

EXAMPLES:

```
sage: t = words.ThueMorseWord(); t
word: 0110100110010110100101100110100110010110...
```

class sage.combinat.words.word_generators.**LowerChristoffelWord**(*p*, *q*, *alphabet=(0, 1)*, *algorithm='cf'*)

Bases: *FiniteWord_list*

Returns the lower Christoffel word of slope p/q, where p and q are relatively prime non-negative integers, over the given two-letter alphabet.

The *Christoffel word of slope `p/q`* is obtained from the Cayley graph of $\mathbf{Z}/(p+q)\mathbf{Z}$ with generator q as follows. If $u \to v$ is an edge in the Cayley graph, then $v = u + p \mod p+q$. Label the edge $u \to v$ by `alphabet[1]` if $u < v$ and `alphabet[0]` otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.

EXAMPLES:

```
sage: words.LowerChristoffelWord(4,7)
word: 00100100101
```

```
sage: words.LowerChristoffelWord(4,7,alphabet='ab')
word: aabaabaabab
```

markoff_number()

Return the Markoff number associated to the Christoffel word `self`.

The *Markoff number* of a Christoffel word w is $trace(M(w))/3$, where $M(w)$ is the 2×2 matrix obtained by applying the morphism: 0 -> matrix(2,[2,1,1,1]) 1 -> matrix(2,[5,2,2,1])

EXAMPLES:

```
sage: w0 = words.LowerChristoffelWord(4,7)
sage: w1, w2 = w0.standard_factorization()
sage: (m0,m1,m2) = (w.markoff_number() for w in (w0,w1,w2))                    #␣
↪needs sage.modules
sage: (m0,m1,m2)                                                               #␣
↪needs sage.modules
(294685, 13, 7561)
```

(continues on next page)

(continued from previous page)

```
sage: m0**2 + m1**2 + m2**2 == 3*m0*m1*m2                                    #␣
↪needs sage.modules
True
```

standard_factorization()

Returns the standard factorization of the Christoffel word `self`.

The *standard factorization* of a Christoffel word w is the unique factorization of w into two Christoffel words.

EXAMPLES:

```
sage: w = words.LowerChristoffelWord(5,9)
sage: w
word: 00100100100101
sage: w1, w2 = w.standard_factorization()
sage: w1
word: 001
sage: w2
word: 00100100101
```

```
sage: w = words.LowerChristoffelWord(51,37)
sage: w1, w2 = w.standard_factorization()
sage: w1
word: 0101011010101101
sage: w2
word: 010101101010110101101010110101011010110101...
sage: w1 * w2 == w
True
```

class sage.combinat.words.word_generators.**WordGenerator**

Bases: `object`

Constructor of several famous words.

EXAMPLES:

```
sage: words.ThueMorseWord()
word: 011010011001011010010110011010011001011010...
```

```
sage: words.FibonacciWord()
word: 010010100100101001010010010100100101001010...
```

```
sage: words.ChristoffelWord(5, 8)
word: 0010010100101
```

```
sage: words.RandomWord(10, 4)     # not tested random
word: 1311131221
```

```
sage: words.CodingOfRotationWord(alpha=0.618, beta=0.618)
word: 101011010110110101101011011010110101101011...
```

```
sage: tm = WordMorphism('a->ab,b->ba')
sage: fib = WordMorphism('a->ab,b->a')
sage: tmword = words.ThueMorseWord([0, 1])
sage: from itertools import repeat
```

(continues on next page)

(continued from previous page)

```
sage: words.s_adic(tmword, repeat('a'), {0:tm, 1:fib})
word: abbaababbaabbaabbaababbaababbaabbaababba...
```

Note: To see a list of all word constructors, type `words.` and then hit the `Tab` key. The documentation for each constructor includes information about each word, which provides a useful reference.

BaumSweetWord()

Returns the Baum-Sweet Word.

The Baum-Sweet Sequence is an infinite word over the alphabet $\{0, 1\}$ defined by the following string substitution rules:

$00 \to 0000$

$01 \to 1001$

$10 \to 0100$

$11 \to 1101$

The substitution rule above can be considered as a morphism on the submonoid of $\{0, 1\}$ generated by $\{00, 01, 10, 11\}$ (which is a free monoid on these generators).

It is also defined as the concatenation of the terms from the Baum-Sweet Sequence:

$$b_n = \begin{cases} 0, & \text{if } n = 0 \\ 1, & \text{if } m \text{ is even} \\ b_{\frac{m-1}{2}}, & \text{if } m \text{ is odd} \end{cases}$$

where $n = m4^k$ and m is not divisible by 4 if $m \neq 0$.

The individual terms of the Baum-Sweet Sequence are also given by:

$$b_n = \begin{cases} 1, & \text{if the binary representation of} n \text{ contains no block of consecutive 0's of odd length} \\ 0, & \text{otherwise} \end{cases}$$

for $n > 0$ with $b_0 = 1$.

For more information see: Wikipedia article Baum-Sweet_sequence.

EXAMPLES:

Baum-Sweet Word:

```
sage: w = words.BaumSweetWord(); w
word: 11011001010010011001000001001001010010001...
```

Block Definition:

```
sage: w = words.BaumSweetWord()
sage: f = lambda n: '1' if all(len(x)%2==0 for x in bin(n)[2:].split('1'))␣
↪else '0'
sage: all(f(i) == w[i] for i in range(1,100))
True
```

CharacteristicSturmianWord(*slope*, *alphabet=(0, 1)*, *bits=None*)

Returns the characteristic Sturmian word (also called standard Sturmian word) of given slope.

Over a binary alphabet $\{a, b\}$, the characteristic Sturmian word c_α of irrational slope α is the infinite word satisfying $s_{\alpha,0} = ac_\alpha$ and $s'_{\alpha,0} = bc_\alpha$, where $s_{\alpha,0}$ and $s'_{\alpha,0}$ are respectively the lower and upper mechanical words with slope α and intercept 0. Equivalently, for irrational α, $c_\alpha = s_{\alpha,\alpha} = s'_{\alpha,\alpha}$.

Let $\alpha = [0, d_1 + 1, d_2, d_3, \ldots]$ be the continued fraction expansion of α. It has been shown that the characteristic Sturmian word of slope α is also the limit of the sequence: $s_0 = b, s_1 = a, \ldots, s_{n+1} = s_n^{d_n} s_{n-1}$ for $n > 0$.

See Section 2.1 of [Loth02] for more details.

INPUT:

- `slope` – the slope of the word. It can be one of the following:
  - real number in $]0, 1[$
  - iterable over the continued fraction expansion of a real number in $]0, 1[$
- `alphabet` – any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, …)
- `bits` – integer (optional and considered only if `slope` is a real number) the number of bits to consider when computing the continued fraction.

OUTPUT:

word

ALGORITHM:

Let $[0, d_1 + 1, d_2, d_3, \ldots]$ be the continued fraction expansion of α. Then, the characteristic Sturmian word of slope α is the limit of the sequence: $s_0 = b$, $s_1 = a$ and $s_{n+1} = s_n^{d_n} s_{n-1}$ for $n > 0$.

EXAMPLES:

From real slope:

```
sage: words.CharacteristicSturmianWord(1/golden_ratio^2)                    #␣
↪needs sage.symbolic
word: 0100101001001010010100100101001001010010...
sage: words.CharacteristicSturmianWord(4/5)                                 #␣
↪needs sage.rings.real_mpfr
word: 11110
sage: words.CharacteristicSturmianWord(5/14)                                #␣
↪needs sage.rings.real_mpfr
word: 01001001001001
sage: words.CharacteristicSturmianWord(pi - 3)                              #␣
↪needs sage.symbolic
word: 0000001000000100000010000001000000100000...
```

From an iterator of the continued fraction expansion of a real:

```
sage: def cf():
....:     yield 0
....:     yield 2
....:     while True: yield 1
sage: F = words.CharacteristicSturmianWord(cf()); F                         #␣
↪needs sage.rings.real_mpfr
word: 0100101001001010010100100101001001010010...
```

(continues on next page)

(continued from previous page)

```
sage: Fib = words.FibonacciWord(); Fib
word: 01001010010010100101001001010010010100100...
sage: F[:10000] == Fib[:10000]                                                  #␣
↪needs sage.rings.real_mpfr
True
```

The alphabet may be specified:

```
sage: words.CharacteristicSturmianWord(cf(), 'rs')                              #␣
↪needs sage.rings.real_mpfr
word: rsrrsrsrrsrrsrsrrsrsrrsrrsrsrrsrrsrsrrsr...
```

The characteristic sturmian word of slope $(\sqrt{3}-1)/2$:

```
sage: words.CharacteristicSturmianWord((sqrt(3)-1)/2)                           #␣
↪needs sage.symbolic
word: 01001001010010010010100100100101001001010...
```

The same word defined from the continued fraction expansion of $(\sqrt{3}-1)/2$:

```
sage: from itertools import cycle, chain
sage: it = chain([0], cycle([2, 1]))
sage: words.CharacteristicSturmianWord(it)
word: 01001001010010010010100100100101001001010...
```

The first terms of the standard sequence of the characteristic sturmian word of slope $(\sqrt{3}-1)/2$:

```
sage: words.CharacteristicSturmianWord([0,2])
word: 01
sage: words.CharacteristicSturmianWord([0,2,1])
word: 010
sage: words.CharacteristicSturmianWord([0,2,1,2])
word: 01001001
sage: words.CharacteristicSturmianWord([0,2,1,2,1])
word: 01001001010
sage: words.CharacteristicSturmianWord([0,2,1,2,1,2])
word: 0100100101001001001010010010010
sage: words.CharacteristicSturmianWord([0,2,1,2,1,2,1])
word: 01001001010010010010100100100101001001010...
```

ChristoffelWord

alias of *LowerChristoffelWord*

CodingOfRotationWord(*alpha*, *beta*, *x=0*, *alphabet=(0, 1)*)

Returns the infinite word obtained from the coding of rotation of parameters (α, β, x) over the given two-letter alphabet.

The *coding of rotation* corresponding to the parameters (α, β, x) is the symbolic sequence $u = (u_n)_{n\geq 0}$ defined over the binary alphabet $\{0, 1\}$ by $u_n = 1$ if $x + n\alpha \in [0, \beta[$ and $u_n = 0$ otherwise. See [AC03].

EXAMPLES:

```
sage: alpha = 0.45
sage: beta = 0.48
sage: words.CodingOfRotationWord(0.45, 0.48)
word: 11010101010010101010110101010010010101010...
```

```
sage: words.CodingOfRotationWord(0.45, 0.48, alphabet='xy')
word: yyxyxyxyxyxyxyxyxyxyxyyxyxyxyxyxyxyxyxyxyx...
```

FibonacciWord(*alphabet=(0, 1)*, *construction_method='recursive'*)

Returns the Fibonacci word on the given two-letter alphabet.

INPUT:

- `alphabet` – any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)
- `construction_method` – can be any of the following: "recursive", "fixed point", "function" (see below for definitions).

Recursive construction: the Fibonacci word is the limit of the following sequence of words: $S_0 = 0$, $S_1 = 01$, $S_n = S_{n-1}S_{n-2}$ for $n \geq 2$.

Fixed point construction: the Fibonacci word is the fixed point of the morphism: $0 \mapsto 01$ and $1 \mapsto 0$. Hence, it can be constructed by the following read-write process:

1. beginning at the first letter of 01,
2. if the next letter is 0, append 01 to the word;
3. if the next letter is 1, append 1 to the word;
4. move to the next letter of the word.

Function: Over the alphabet $\{1, 2\}$, the n-th letter of the Fibonacci word is $\lfloor (n+2)\varphi \rfloor - \lfloor (n+1)\varphi \rfloor$ where $\varphi = (1+\sqrt{5})/2$ is the golden ratio.

EXAMPLES:

```
sage: w = words.FibonacciWord(construction_method="recursive"); w
word: 0100101001001010010100100101001001010010...
```

```
sage: v = words.FibonacciWord(construction_method="recursive", alphabet='ab');
↪ v
word: abaababaabaababaababaabaababaabaababaaba...
```

```
sage: u = words.FibonacciWord(construction_method="fixed point"); u
word: 0100101001001010010100100101001001010010...
```

```
sage: words.FibonacciWord(construction_method="fixed point", alphabet=[4, 1])
word: 4144141441441414414414414414414414414414...
```

```
sage: words.FibonacciWord([0,1], 'function')                                #␣
↪needs sage.symbolic
word: 0100101001001010010100100101001001010010...
sage: words.FibonacciWord('ab', 'function')                                 #␣
↪needs sage.symbolic
word: abaababaabaababaababaabaababaabaababaaba...
```

FixedPointOfMorphism(*morphism*, *first_letter*)

Returns the fixed point of the morphism beginning with `first_letter`.

A *fixed point* of a morphism φ is a word w such that $\varphi(w) = w$.

INPUT:

- `morphism` – endomorphism prolongable on `first_letter`. It must be something that WordMorphism's constructor understands (dict, str, ...).
- `first_letter` – the first letter of the fixed point

OUTPUT:

The fixed point of the morphism beginning with `first_letter`

EXAMPLES:

```
sage: mu = {0:[0,1], 1:[1,0]}
sage: tm = words.FixedPointOfMorphism(mu,0); tm
word: 0110100110010110100101100110100110010110...
sage: TM = words.ThueMorseWord()
sage: tm[:1000] == TM[:1000]                                                #␣
↪needs sage.modules
True
```

```
sage: mu = {0:[0,1], 1:[0]}
sage: f = words.FixedPointOfMorphism(mu,0); f
word: 0100101001001010010100100101001001010010...
sage: F = words.FibonacciWord(); F
word: 0100101001001010010100100101001001010010...
sage: f[:1000] == F[:1000]                                                  #␣
↪needs sage.modules
True
```

```
sage: fp = words.FixedPointOfMorphism('a->abc,b->,c->','a'); fp
word: abc
```

KolakoskiWord(*alphabet=(1, 2)*)

Returns the Kolakoski word over the given alphabet and starting with the first letter of the alphabet.

Let $A = \{a, b\}$ be an alphabet, where a and b are two distinct positive integers. The Kolakoski word $K_{a,b}$ over A and starting with a is the unique infinite word w such that $w = \Delta(w)$, where $\Delta(w)$ is the word encoding the runs of w (see `delta()` method on words for more details).

Note that $K_{a,b} \neq K_{b,a}$. On the other hand, the words $K_{a,b}$ and $K_{b,a}$ are the unique two words over A that are fixed by Δ.

Also note that the Kolakoski word is also known as the Oldenburger word.

INPUT:

- `alphabet` – (default: (1,2)) an iterable of two positive integers

OUTPUT:

infinite word

EXAMPLES:

The usual Kolakoski word:

```
sage: w = words.KolakoskiWord()
sage: w
word: 1221121221221121122121121221121121221221...
sage: w.delta()
word: 1221121221221121122121121221121121221221...
```

The other Kolakoski word on the same alphabet:

```
sage: w = words.KolakoskiWord(alphabet = (2,1))
sage: w
word: 2211212212211211221211212211211212212211...
sage: w.delta()
word: 2211212212211211221211212211211212212211...
```

It is naturally generalized to any two integers alphabet:

```
sage: w = words.KolakoskiWord(alphabet = (2,5))
sage: w
word: 2255222225555522552255225555522222555552...
sage: w.delta()
word: 2255222225555522552255225555522222555552...
```

REFERENCES:

LowerChristoffelWord

alias of *LowerChristoffelWord*

LowerMechanicalWord(*alpha*, *rho=0*, *alphabet=None*)

Returns the lower mechanical word with slope α and intercept ρ

The lower mechanical word $s_{\alpha,\rho}$ with slope α and intercept ρ is defined by $s_{\alpha,\rho}(n) = \lfloor\alpha(n+1)+\rho\rfloor - \lfloor\alpha n+\rho\rfloor$. [Loth02]

INPUT:

- `alpha` – real number such that $0 \leq \alpha \leq 1$
- `rho` – real number (default: 0)
- `alphabet` – iterable of two elements or `None` (default: `None`)

OUTPUT:

infinite word

EXAMPLES:

```
sage: words.LowerMechanicalWord(1/golden_ratio^2)                              #␣
↪needs sage.symbolic
word: 0010010100100101001010010010100100101001...
sage: words.LowerMechanicalWord(1/5)                                           #␣
↪needs sage.symbolic
word: 0000100001000010000100001000010000100001...
sage: words.LowerMechanicalWord(1/pi)                                          #␣
↪needs sage.symbolic
word: 0001001001001001001001000100100100100100...
```

MinimalSmoothPrefix(*n*)

This function finds and returns the minimal smooth prefix of length `n`.

See [BMP2007] for a definition.

INPUT:

- `n` – the desired length of the prefix

OUTPUT:

word – the prefix

Note: Be patient, this function can take a really long time if asked for a large prefix.

EXAMPLES:

```
sage: words.MinimalSmoothPrefix(10)
word: 1212212112
```

PalindromicDefectWord(*k=1*, *alphabet='ab'*)

Return the finite word $w = ab^k ab^{k-1} aab^{k-1} ab^k a$.

As described by Brlek, Hamel, Nivat and Reutenauer in [BHNR2004], this finite word w is such that the infinite periodic word w^ω has palindromic defect `k`.

INPUT:

- `k` – positive integer (default: 1)
- `alphabet` – iterable (default: `'ab'`) of size two

OUTPUT:

finite word

EXAMPLES:

```
sage: words.PalindromicDefectWord(10)
word: abbbbbbbbbbabbbbbbbbbaabbbbbbbbbbabbbbbbb...
```

```
sage: w = words.PalindromicDefectWord(3)
sage: w
word: abbbabbaabbabbba
sage: w.defect()
0
sage: (w^2).defect()
3
sage: (w^3).defect()
3
```

On other alphabets:

```
sage: words.PalindromicDefectWord(3, alphabet='cd')
word: cdddcddccddcdddc
sage: words.PalindromicDefectWord(3, alphabet=['c', 3])
word: c333c33cc33c333c
```

RandomWord(*n*, *m=2*, *alphabet=None*)

Return a random word of length n over the given m-letter alphabet.

INPUT:

- `n` – integer, the length of the word
- `m` – integer (default 2), the size of the output alphabet
- `alphabet` – (default is $\{0, 1, ..., m-1\}$) any container of length m that is suitable to build an instance of OrderedAlphabet (list, tuple, str, …)

EXAMPLES:

```
sage: words.RandomWord(10)          # random results
word: 0110100101
sage: words.RandomWord(10, 4)       # random results
word: 0322313320
sage: words.RandomWord(100, 7)      # random results
word: 26306440236425164426500256113000344133 10...
sage: words.RandomWord(100, 7, range(-3,4))  # random results
word: 1,3,-1,-1,3,2,2,0,1,-2,1,-1,-3,-2,2,0,3,0,-3,0,3,0,-2,-2,2,0,1,-3,2,-2,-
↪2,2,0,2,1,-2,-3,-2,-1,0,...
sage: words.RandomWord(100, 5, "abcde") # random results
word: acebeaaccdbedbbbdeadeebbdeeebeaaacbadaac...
sage: words.RandomWord(17, 5, "abcde")     # random results
word: dcacbbecbddebaadd
```

StandardEpisturmianWord(*directive_word*)

Returns the standard episturmian word (or epistandard word) directed by directive_word. Over a 2-letter alphabet, this function gives characteristic Sturmian words.

An infinite word w over a finite alphabet A is said to be *standard episturmian* (or *epistandard*) iff there exists an infinite word $x_1x_2x_3\cdots$ over A (called the *directive word* of w) such that w is the limit as n goes to infinity of $Pal(x_1\cdots x_n)$, where Pal is the iterated palindromic closure function.

Note that an infinite word is *episturmian* if it has the same set of factors as some epistandard word.

See for instance [DJP2001], [JP2002], and [GJ2007].

INPUT:

- `directive_word` – an infinite word or a period of a periodic infinite word

EXAMPLES:

```
sage: Fibonacci = words.StandardEpisturmianWord(Words('ab')('ab')); Fibonacci
word: abaababaabaababaabaababaabaababaabaababaaba...
sage: Tribonacci = words.StandardEpisturmianWord(Words('abc')('abc'));␣
↪Tribonacci
word: abacabaabacababacabaabacabacabaabacababa...
sage: S = words.StandardEpisturmianWord(Words('abcd')('aabcabada')); S
word: aabaacaabaaabaacaabaabaacaabaaabaacaabaa...
sage: S = words.StandardEpisturmianWord(Fibonacci); S
word: abaabaababaabaababaabaababaabaababaabaabab...
sage: S[:25]
word: abaabaababaabaababaabaaba
sage: S = words.StandardEpisturmianWord(Tribonacci); S
word: abaabacabaabaabacabaababaabacabaabaabaca...
sage: words.StandardEpisturmianWord(123)
Traceback (most recent call last):
...
TypeError: directive_word is not a word, so it cannot be used to build an␣
↪episturmian word
sage: words.StandardEpisturmianWord(Words('ab'))
Traceback (most recent call last):
...
TypeError: directive_word is not a word, so it cannot be used to build an␣
↪episturmian word
```

ThueMorseWord(*alphabet=(0, 1)*, *base=2*)

Returns the (Generalized) Thue-Morse word over the given alphabet.

There are several ways to define the Thue-Morse word t. We use the following definition: $t[n]$ is the sum modulo m of the digits in the given base expansion of n.

See [BmBGL07], [Brlek89], and [MH38].

INPUT:

- `alphabet` – (default: (0, 1)) any container that is suitable to build an instance of OrderedAlphabet (list, tuple, str, …)
- `base` – an integer (default : 2) greater or equal to 2

EXAMPLES:

Thue-Morse word:

```
sage: t = words.ThueMorseWord(); t
word: 0110100110010110100101100110100110010110...
```

Thue-Morse word on other alphabets:

```
sage: t = words.ThueMorseWord('ab'); t
word: abbabaabbaababbabaababbaabbabaabbaababba...
```

```
sage: t = words.ThueMorseWord(['L1', 'L2'])
sage: t[:8]
word: L1,L2,L2,L1,L2,L1,L1,L2
```

Generalized Thue Morse word:

```
sage: words.ThueMorseWord(alphabet=(0,1,2), base=2)
word: 0112122012202001122020012001011212202001...
sage: t = words.ThueMorseWord(alphabet=(0,1,2), base=5); t
word: 0120112012201200120112012120122012001201...
sage: t[100:130].critical_exponent()
10/3
```

REFERENCES:

UpperChristoffelWord(*p*, *q*, *alphabet=(0, 1)*)

Returns the upper Christoffel word of slope p/q, where p and q are relatively prime non-negative integers, over the given alphabet.

The *upper Christoffel word of slope `p/q`* is equal to the reversal of the lower Christoffel word of slope p/q. Equivalently, if xuy is the lower Christoffel word of slope p/q, where x and y are letters, then yux is the upper Christoffel word of slope p/q (because u is a palindrome).

INPUT:

- `alphabet` – any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, …)

EXAMPLES:

```
sage: words.UpperChristoffelWord(1,0)
word: 1
```

```
sage: words.UpperChristoffelWord(0,1)
word: 0
```

```
sage: words.UpperChristoffelWord(1,1)
word: 10
```

```
sage: words.UpperChristoffelWord(4,7)
word: 10100100100
```

UpperMechanicalWord(*alpha*, *rho=0*, *alphabet=None*)

Returns the upper mechanical word with slope α and intercept ρ

The upper mechanical word $s'_{\alpha,\rho}$ with slope α and intercept ρ is defined by $s'_{\alpha,\rho}(n) = \lceil \alpha(n+1)+\rho \rceil - \lceil \alpha n + \rho \rceil$. [Loth02]

INPUT:

- `alpha` – real number such that $0 \leq \alpha \leq 1$
- `rho` – real number (default: 0)
- `alphabet` – iterable of two elements or `None` (default: `None`)

OUTPUT:

infinite word

EXAMPLES:

```
sage: words.UpperMechanicalWord(1/golden_ratio^2)                              #␣
↪needs sage.symbolic

Path: 3212303230103230321232101232123032123210...
```

fibonacci_tile(*n*)

Returns the n-th Fibonacci Tile [BmBGL09].

EXAMPLES:

```
sage: for i in range(3): words.fibonacci_tile(i)                               #␣
↪needs sage.modules
Path: 3210
Path: 323030101212
Path: 3230301030323212323032321210121232121010...
```

s_adic(*sequence*, *letters*, *morphisms=None*)

Returns the s-adic infinite word obtained from a sequence of morphisms applied on a letter.

DEFINITION (from [Fogg]):

Let w be a infinite word over an alphabet $A = A_0$. A standard representation of w is obtained from a sequence of substitutions $\sigma_k : A_{k+1} \to A_k$ and a sequence of letters $a_k \in A_k$ such that:

$$\lim_{k\to\infty} \sigma_0 \circ \sigma_1 \circ \cdots \sigma_k(a_k).$$

Given a set of substitutions S, we say that the representation is S-adic standard if the substitutions are chosen in S.

INPUT:

- `sequence` – An iterable sequence of indices or of morphisms. It may be finite or infinite. If `sequence` is infinite, the image of the $(i+1)$-th letter under the $(i+1)$-th morphism must start with the i-th letter.
- `letters` – A letter or a sequence of letters.
- `morphisms` – dict, list, callable or `None` (default: `None`) an object that maps indices to morphisms. If `None`, then `sequence` must consist of morphisms.

OUTPUT:

A word.

EXAMPLES:

Let us define three morphisms and compute the first nested successive prefixes of the s-adic word:

```
sage: m1 = WordMorphism('e->gh,f->hg')
sage: m2 = WordMorphism('c->ef,d->e')
sage: m3 = WordMorphism('a->cd,b->dc')
sage: words.s_adic([m1],'e')
word: gh
sage: words.s_adic([m1,m2],'ec')
word: ghhg
sage: words.s_adic([m1,m2,m3],'eca')
word: ghhggh
```

When the given sequence of morphism is finite, one may simply give the last letter, i.e. `'a'`, instead of giving all of them, i.e. `'eca'`:

```
sage: words.s_adic([m1,m2,m3],'a')
word: ghhggh
sage: words.s_adic([m1,m2,m3],'b')
word: ghghhg
```

If the letters don't satisfy the hypothesis of the algorithm (nested prefixes), an error is raised:

```
sage: words.s_adic([m1,m2,m3],'ecb')
Traceback (most recent call last):
...
ValueError: the hypothesis of the algorithm used is not satisfied; the image␣
↪of the 3-th letter (=b) under the 3-th morphism (=a->cd, b->dc) should␣
↪start with the 2-th letter (=c)
```

Let's define the Thue-Morse morphism and the Fibonacci morphism which will be used below to illustrate more examples and let's import the `repeat` tool from the `itertools`:

```
sage: tm = WordMorphism('a->ab,b->ba')
sage: fib = WordMorphism('a->ab,b->a')
sage: from itertools import repeat
```

Two trivial examples of infinite s-adic words:

```
sage: words.s_adic(repeat(tm),repeat('a'))
word: abbabaabbaababbabaababbaabbabaabbaababba...
```

```
sage: words.s_adic(repeat(fib),repeat('a'))
word: abaababaabaababaababaabaababaabaababaaba...
```

A less trivial infinite s-adic word:

```
sage: D = {4:tm,5:fib}
sage: tmword = words.ThueMorseWord([4,5])
sage: it = (D[a] for a in tmword)
sage: words.s_adic(it, repeat('a'))
word: abbaababbaabbaabbaababbaababbaabbaababba...
```

The same thing using a sequence of indices:

```
sage: tmword = words.ThueMorseWord([0,1])
sage: words.s_adic(tmword, repeat('a'), [tm,fib])
word: abbaababbaabbaabbaababbaababbaabbaababba...
```

The correspondence of the indices may be given as a dict:

```
sage: words.s_adic(tmword, repeat('a'), {0:tm,1:fib})
word: abbaababbaabbaabbaababbaababbaabbaababba...
```

because dict are more versatile for indices:

```
sage: tmwordTF = words.ThueMorseWord('TF')
sage: words.s_adic(tmwordTF, repeat('a'), {'T':tm,'F':fib})
word: abbaababbaabbaabbaababbaababbaabbaababba...
```

or by a callable:

```
sage: f = lambda n: tm if n == 0 else fib
sage: words.s_adic(words.ThueMorseWord(), repeat('a'), f)
word: abbaababbaabbaabbaababbaababbaabbaababba...
```

Random infinite s-adic words:

```
sage: from sage.misc.prandom import randint
sage: def it():
....:   while True: yield randint(0,1)
sage: words.s_adic(it(), repeat('a'), [tm,fib])  # random
word: abbaababababbaababbaabbaababbaababbaabba...
sage: words.s_adic(it(), repeat('a'), [tm,fib])  # random
word: abbaababbaabbaababbaababbaabbaababbaabba...
sage: words.s_adic(it(), repeat('a'), [tm,fib])  # random
word: abaaababaabaabaaababaabaaababaabaaababaa...
```

An example where the sequences cycle on two morphisms and two letters:

```
sage: G = WordMorphism('a->cd,b->dc')
sage: H = WordMorphism('c->ab,d->ba')
sage: from itertools import cycle
sage: words.s_adic([G,H],'ac')
word: cddc
sage: words.s_adic(cycle([G,H]),cycle('ac'))
word: cddcdccddccdcddcdccdcddccddcdccddccdcddc...
```

The morphism $\sigma : a \mapsto ba, b \mapsto b$ can't satisfy the hypothesis of the nested prefixes, but one may compute arbitrarily long finite words having the limit $\sigma^\omega(a)$:

```
sage: sigma = WordMorphism('a->ba,b->b')
sage: words.s_adic(repeat(sigma),repeat('a'))
Traceback (most recent call last):
...
ValueError: the hypothesis of the algorithm used is not satisfied; the image␣
↪of the 2-th letter (=a) under the 2-th morphism (=a->ba, b->b) should start␣
↪with the 1-th letter (=a)
sage: words.s_adic([sigma],'a')
word: ba
sage: words.s_adic([sigma,sigma],'a')
word: bba
sage: words.s_adic([sigma]*3,'a')
word: bbba
sage: words.s_adic([sigma]*4,'a')
word: bbbba
sage: words.s_adic([sigma]*5,'a')
word: bbbbba
sage: words.s_adic([sigma]*6,'a')
word: bbbbbba
sage: words.s_adic([sigma]*7,'a')
word: bbbbbbba
```

The following examples illustrates an S-adic word defined over an infinite set S of morphisms x_h:

```
sage: x = lambda h:WordMorphism({1:[2],2:[3]+[1]*(h+1),3:[3]+[1]*h})
sage: for h in [0,1,2,3]:
....:     print("{} {}".format(h, x(h)))
0 1->2, 2->31, 3->3
1 1->2, 2->311, 3->31
2 1->2, 2->3111, 3->311
3 1->2, 2->31111, 3->3111
sage: w = Word(lambda n : valuation(n+1, 2) ); w
word: 0102010301020104010201030102010501020103...
sage: s = words.s_adic(w, repeat(3), x); s
word: 32322322323223223223223223223232232232232...
sage: prefixe = s[:10000]
sage: list(map(prefixe.number_of_factors, range(15)))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
sage: [_[i+1] - _[i] for i in range(len(_)-1)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

- Sébastien Labbé (2009-12-18): initial version

5.1.369 Datatypes for words defined by iterators and callables

class sage.combinat.words.word_infinite_datatypes.**WordDatatype_callable**(*parent*, *callable*, *length=None*)

Bases: *WordDatatype*

Datatype for a word defined by a callable.

class sage.combinat.words.word_infinite_datatypes.**WordDatatype_callable_with_caching**(*parent*, *callable*, *length=*

Bases: *WordDatatype_callable*

Datatype for a word defined by a callable.

flush()

Empty the associated cache of letters.

EXAMPLES:

The first 40 (by default) values are always cached:

```
sage: w = words.ThueMorseWord()
sage: w._letter_cache
{0: 0, 1: 1, 2: 1, 3: 0, 4: 1, 5: 0, 6: 0, 7: 1, 8: 1, 9: 0, 10: 0, 11: 1,␣
↪12: 0, 13: 1, 14: 1, 15: 0, 16: 1, 17: 0, 18: 0, 19: 1, 20: 0, 21: 1, 22: 1,
↪ 23: 0, 24: 0, 25: 1, 26: 1, 27: 0, 28: 1, 29: 0, 30: 0, 31: 1, 32: 1, 33:␣
↪0, 34: 0, 35: 1, 36: 0, 37: 1, 38: 1, 39: 0}
sage: w[100]
1
sage: w._letter_cache
{0: 0, 1: 1, 2: 1, 3: 0, 4: 1, 5: 0, 6: 0, 7: 1, 8: 1, 9: 0, 10: 0, 11: 1,␣
↪12: 0, 13: 1, 14: 1, 15: 0, 16: 1, 17: 0, 18: 0, 19: 1, 20: 0, 21: 1, 22: 1,
↪ 23: 0, 24: 0, 25: 1, 26: 1, 27: 0, 28: 1, 29: 0, 30: 0, 31: 1, 32: 1, 33:␣
↪0, 34: 0, 35: 1, 36: 0, 37: 1, 38: 1, 39: 0, 100: 1}
sage: w.flush()
sage: w._letter_cache
{}
```

class sage.combinat.words.word_infinite_datatypes.**WordDatatype_iter**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype*

INPUT:

- `parent` – a parent
- `iter` – an iterator
- `length` – (default: `None`) the length of the word

EXAMPLES:

```
sage: w = Word(iter("abbabaab"), length="unknown", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
```

(continues on next page)

(continued from previous page)

```
sage: w.length() is None
False
sage: w.length()
8
sage: s = "abbabaabbaababbabaabababbaabbabaabbaababbaabbabaabab"
sage: w = Word(iter(s), length="unknown", caching=False); w
word: abbabaabbaababbabaabababbaabbabaabbaababba...
sage: w.length() is None
True
```

```
sage: w = Word(iter("abbabaab"), length="finite", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8, caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
```

class sage.combinat.words.word_infinite_datatypes.**WordDatatype_iter_with_caching**(*parent*, *iter*, *length=None*)

Bases: *WordDatatype_iter*

INPUT:

- `parent` – a parent
- `iter` – an iterator
- `length` – (default: `None`) the length of the word

EXAMPLES:

```
sage: import itertools
sage: Word(itertools.cycle("abbabaab"))
word: abbabaababbabaababbabaababbabaababbabaab...
sage: w = Word(iter("abbabaab"), length="finite"); w
word: abbabaab
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length="unknown"); w
word: abbabaab
sage: w.length()
8
sage: list(w)
['a', 'b', 'b', 'a', 'b', 'a', 'a', 'b']
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8)
sage: w._len
8
```

flush()

Delete the cached values.

EXAMPLES:

```
sage: from itertools import count
sage: w = Word(count())
sage: w._last_index, len(w._list)
(39, 40)
sage: w[43]
43
sage: w._last_index, len(w._list)
(43, 44)
sage: w.flush()
sage: w._last_index, w._list
(-1, [])
```

5.1.370 User-customizable options for words

sage.combinat.words.word_options.**WordOptions**(***kwargs*)

Sets the global options for elements of the word class. The defaults are for words to be displayed in list notation.

INPUT:

- `display` – 'string' (default), or 'list', words are displayed in string or list notation.
- `truncate` – boolean (default: `True`), whether to truncate the string output of long words (see truncate_length below).
- `truncate_length` – integer (default: 40), if the length of the word is greater than this integer, then the word is truncated.
- `letter_separator` – (string, default: ",") if the string representation of letters have length greater than 1, then the letters are separated by this string in the string representation of the word.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: w = Word([2,1,3,12])
sage: u = Word("abba")
sage: WordOptions(display='list')
sage: w
word: [2, 1, 3, 12]
sage: u
word: ['a', 'b', 'b', 'a']
sage: WordOptions(display='string')
sage: w
word: 2,1,3,12
sage: u
word: abba
```

5.1.371 Set of words

To define a new class of words, please refer to the documentation file: sage/combinat/words/notes/word_inheritance_howto.rst

AUTHORS:

- Franco Saliola (2008-12-17): merged into sage
- Sebastien Labbe (2008-12-17): merged into sage
- Arnaud Bergeron (2008-12-17): merged into sage
- Sebastien Labbe (2009-07-21): Improved morphism iterator (Issue #6571).
- Vincent Delecroix (2015): classes simplifications (Issue #19619)

EXAMPLES:

```
sage: Words()
Finite and infinite words over Set of Python objects of class 'object'
sage: Words(4)
Finite and infinite words over {1, 2, 3, 4}
sage: Words(4,5)
Words of length 5 over {1, 2, 3, 4}

sage: FiniteWords('ab')
Finite words over {'a', 'b'}
sage: InfiniteWords('natural numbers')
Infinite words over Non negative integers
```

class sage.combinat.words.words.**AbstractLanguage**(*alphabet=None*, *category=None*)

Bases: Parent

Abstract base class

This is *not* to be used by any means. This class gather previous features of set of words (prior to Issue #19619). In the future that class might simply disappear or become a common base class for all languages. In the latter case, its name would possibly change to Language.

alphabet()

EXAMPLES:

```
sage: Words(NN).alphabet()
Non negative integer semiring

sage: InfiniteWords([1,2,3]).alphabet()
{1, 2, 3}
sage: InfiniteWords('ab').alphabet()
{'a', 'b'}

sage: FiniteWords([1,2,3]).alphabet()
{1, 2, 3}
sage: FiniteWords().alphabet()
Set of Python objects of class 'object'
```

identity_morphism()

Returns the identity morphism from self to itself.

EXAMPLES:

```
sage: W = Words('ab')
sage: W.identity_morphism()
WordMorphism: a->a, b->b
```

```
sage: W = Words(range(3))
sage: W.identity_morphism()
WordMorphism: 0->0, 1->1, 2->2
```

There is no support yet for infinite alphabet:

```
sage: W = Words(alphabet=Alphabet(name='NN'))
sage: W
Finite and infinite words over Non negative integers
sage: W.identity_morphism()
Traceback (most recent call last):
...
NotImplementedError: size of alphabet must be finite
```

class sage.combinat.words.words.**FiniteOrInfiniteWords**(*alphabet*)

Bases: *AbstractLanguage*

INPUT:

- `alphabet` – the underlying alphabet

cardinality()

Return the cardinality of this set of words.

EXAMPLES:

```
sage: Words('abcd').cardinality()
+Infinity
sage: Words('a').cardinality()
+Infinity
sage: Words('').cardinality()
1
```

factors()

Return the set of finite words.

EXAMPLES:

```
sage: Words('ab').finite_words()
Finite words over {'a', 'b'}
```

finite_words()

Return the set of finite words.

EXAMPLES:

```
sage: Words('ab').finite_words()
Finite words over {'a', 'b'}
```

infinite_words()

Return the set of infinite words.

EXAMPLES:

```
sage: Words('ab').infinite_words()
Infinite words over {'a', 'b'}
```

iterate_by_length(*length*)

Return an iterator over the words of given length.

EXAMPLES:

```
sage: [w.string_rep() for w in Words('ab').iterate_by_length(3)]
['aaa', 'aab', 'aba', 'abb', 'baa', 'bab', 'bba', 'bbb']
```

shift()

Return the set of infinite words.

EXAMPLES:

```
sage: Words('ab').infinite_words()
Infinite words over {'a', 'b'}
```

class sage.combinat.words.words.**FiniteWords**(*alphabet=None*, *category=None*)

Bases: *AbstractLanguage*

The set of finite words over a fixed alphabet.

EXAMPLES:

```
sage: W = FiniteWords('ab')
sage: W
Finite words over {'a', 'b'}
```

cardinality()

Return the cardinality of this set.

EXAMPLES:

```
sage: FiniteWords('').cardinality()
1
sage: FiniteWords('a').cardinality()
+Infinity
```

factors()

Return itself.

EXAMPLES:

```
sage: FiniteWords('ab').factors()
Finite words over {'a', 'b'}
```

iter_morphisms(*arg=None*, *codomain=None*, *min_length=1*)

Iterate over all morphisms with domain `self` and the given codomain.

INPUT:

- `arg` – (default: `None`) It can be one of the following:
  - `None` – then the method iterates through all morphisms.
  - tuple (a, b) of two integers – It specifies the range `range(a, b)` of values to consider for the sum of the length of the image of each letter in the alphabet.

  - list of nonnegative integers – The length of the list must be equal to the size of the alphabet, and the i-th integer of `arg` determines the length of the word mapped to by the i-th letter of the (ordered) alphabet.

- `codomain` – (default: `None`) a combinatorial class of words. By default, `codomain` is `self`.
- `min_length` – (default: 1) nonnegative integer. If `arg` is not specified, then iterate through all the morphisms where the length of the images of each letter in the alphabet is at least `min_length`. This is ignored if `arg` is a list.

OUTPUT:

iterator

EXAMPLES:

Iterator over all non-erasing morphisms:

```
sage: W = FiniteWords('ab')
sage: it = W.iter_morphisms()
sage: for _ in range(7): next(it)
WordMorphism: a->a, b->a
WordMorphism: a->a, b->b
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
```

Iterator over all morphisms including erasing morphisms:

```
sage: W = FiniteWords('ab')
sage: it = W.iter_morphisms(min_length=0)
sage: for _ in range(7): next(it)
WordMorphism: a->, b->
WordMorphism: a->a, b->
WordMorphism: a->b, b->
WordMorphism: a->, b->a
WordMorphism: a->, b->b
WordMorphism: a->aa, b->
WordMorphism: a->ab, b->
```

Iterator over morphisms where the sum of the lengths of the images of the letters is in a specific range:

```
sage: for m in W.iter_morphisms((0, 3), min_length=0): m
WordMorphism: a->aa, b->
WordMorphism: a->ab, b->
WordMorphism: a->ba, b->
WordMorphism: a->bb, b->
WordMorphism: a->a, b->a
WordMorphism: a->a, b->b
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
WordMorphism: a->a, b->
WordMorphism: a->b, b->
WordMorphism: a->, b->aa
WordMorphism: a->, b->ab
WordMorphism: a->, b->ba
WordMorphism: a->, b->bb
WordMorphism: a->, b->a
```

(continues on next page)

(continued from previous page)

```
WordMorphism: a->, b->b
WordMorphism: a->, b->
```

```
sage: for m in W.iter_morphisms( (2, 4) ): m
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
WordMorphism: a->ab, b->b
WordMorphism: a->ba, b->a
WordMorphism: a->ba, b->b
WordMorphism: a->bb, b->a
WordMorphism: a->bb, b->b
WordMorphism: a->a, b->aa
WordMorphism: a->a, b->ab
WordMorphism: a->a, b->ba
WordMorphism: a->a, b->bb
WordMorphism: a->b, b->aa
WordMorphism: a->b, b->ab
WordMorphism: a->b, b->ba
WordMorphism: a->b, b->bb
WordMorphism: a->a, b->a
WordMorphism: a->a, b->b
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
```

Iterator over morphisms with specific image lengths:

```
sage: for m in W.iter_morphisms([0, 0]): m
WordMorphism: a->, b->
sage: for m in W.iter_morphisms([0, 1]): m
WordMorphism: a->, b->a
WordMorphism: a->, b->b
sage: for m in W.iter_morphisms([2, 1]): m
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
WordMorphism: a->ab, b->b
WordMorphism: a->ba, b->a
WordMorphism: a->ba, b->b
WordMorphism: a->bb, b->a
WordMorphism: a->bb, b->b
sage: for m in W.iter_morphisms([2, 2]): m
WordMorphism: a->aa, b->aa
WordMorphism: a->aa, b->ab
WordMorphism: a->aa, b->ba
WordMorphism: a->aa, b->bb
WordMorphism: a->ab, b->aa
WordMorphism: a->ab, b->ab
WordMorphism: a->ab, b->ba
WordMorphism: a->ab, b->bb
WordMorphism: a->ba, b->aa
WordMorphism: a->ba, b->ab
WordMorphism: a->ba, b->ba
WordMorphism: a->ba, b->bb
WordMorphism: a->bb, b->aa
WordMorphism: a->bb, b->ab
```

(continues on next page)

(continued from previous page)

```
WordMorphism: a->bb, b->ba
WordMorphism: a->bb, b->bb
```

The codomain may be specified as well:

```
sage: Y = FiniteWords('xyz')
sage: for m in W.iter_morphisms([0, 2], codomain=Y): m
WordMorphism: a->, b->xx
WordMorphism: a->, b->xy
WordMorphism: a->, b->xz
WordMorphism: a->, b->yx
WordMorphism: a->, b->yy
WordMorphism: a->, b->yz
WordMorphism: a->, b->zx
WordMorphism: a->, b->zy
WordMorphism: a->, b->zz
sage: for m in Y.iter_morphisms([0,2,1], codomain=W): m
WordMorphism: x->, y->aa, z->a
WordMorphism: x->, y->aa, z->b
WordMorphism: x->, y->ab, z->a
WordMorphism: x->, y->ab, z->b
WordMorphism: x->, y->ba, z->a
WordMorphism: x->, y->ba, z->b
WordMorphism: x->, y->bb, z->a
WordMorphism: x->, y->bb, z->b
sage: it = W.iter_morphisms(codomain=Y)
sage: for _ in range(10): next(it)
WordMorphism: a->x, b->x
WordMorphism: a->x, b->y
WordMorphism: a->x, b->z
WordMorphism: a->y, b->x
WordMorphism: a->y, b->y
WordMorphism: a->y, b->z
WordMorphism: a->z, b->x
WordMorphism: a->z, b->y
WordMorphism: a->z, b->z
WordMorphism: a->xx, b->x
```

iterate_by_length(*l=1*)

Returns an iterator over all the words of self of length l.

INPUT:

- `l` – integer (default: 1), the length of the desired words

EXAMPLES:

```
sage: W = FiniteWords('ab')
sage: list(W.iterate_by_length(1))
[word: a, word: b]
sage: list(W.iterate_by_length(2))
[word: aa, word: ab, word: ba, word: bb]
sage: list(W.iterate_by_length(3))
[word: aaa,
 word: aab,
 word: aba,
 word: abb,
```

(continues on next page)

(continued from previous page)

```
 word: baa,
 word: bab,
 word: bba,
 word: bbb]
sage: list(W.iterate_by_length('a'))
Traceback (most recent call last):
...
TypeError: the parameter l (='a') must be an integer
```

random_element(*length=None*, **args*, ***kwds*)

Returns a random finite word on the given alphabet.

INPUT:

- `length` – (optional) the length of the word. If not set, will use a uniformly random number between 0 and 10.
- all other argument are transmitted to the random generator of the alphabet

EXAMPLES:

```
sage: W = FiniteWords(5)
sage: W.random_element() # random
word: 5114325445423521544531411434451152142155...

sage: W = FiniteWords(ZZ)
sage: W.random_element() # random
word: 5,-1,-1,-1,0,0,0,0,-3,-11
sage: W.random_element(length=4, x=0, y=4) # random
word: 1003
```

shift()

Return the set of infinite words on the same alphabet.

EXAMPLES:

```
sage: FiniteWords('ab').shift()
Infinite words over {'a', 'b'}
```

class sage.combinat.words.words.**InfiniteWords**(*alphabet=None*, *category=None*)

Bases: *AbstractLanguage*

cardinality()

Return the cardinality of this set

EXAMPLES:

```
sage: InfiniteWords('ab').cardinality()
+Infinity
sage: InfiniteWords('a').cardinality()
1
sage: InfiniteWords('').cardinality()
0
```

factors()

Return the set of finite words on the same alphabet.

EXAMPLES:

```
sage: InfiniteWords('ab').factors()
Finite words over {'a', 'b'}
```

random_element(**args*, ***kwds*)

Return a random infinite word.

EXAMPLES:

```
sage: W = InfiniteWords('ab')
sage: W.random_element() # random
word: abbbabbaabbbabbabbaabaabbabbbbbbbbbaabbbb...

sage: W = InfiniteWords(ZZ)
sage: W.random_element(x=2,y=4) # random
word: 33332233222322333332233232322222233233233...
```

shift()

Return itself.

EXAMPLES:

```
sage: InfiniteWords('ab').shift()
Infinite words over {'a', 'b'}
```

sage.combinat.words.words.**Words**(*alphabet=None*, *length=None*, *finite=True*, *infinite=True*)

Returns the combinatorial class of words of length k over an alphabet.

EXAMPLES:

```
sage: Words()
Finite and infinite words over Set of Python objects of class 'object'
sage: Words(length=7)
Words of length 7 over Set of Python objects of class 'object'
sage: Words(5)
Finite and infinite words over {1, 2, 3, 4, 5}
sage: Words(5, 3)
Words of length 3 over {1, 2, 3, 4, 5}
sage: Words(5, infinite=False)
Finite words over {1, 2, 3, 4, 5}
sage: Words(5, finite=False)
Infinite words over {1, 2, 3, 4, 5}
sage: Words('ab')
Finite and infinite words over {'a', 'b'}
sage: Words('ab', 2)
Words of length 2 over {'a', 'b'}
sage: Words('ab', infinite=False)
Finite words over {'a', 'b'}
sage: Words('ab', finite=False)
Infinite words over {'a', 'b'}
sage: Words('positive integers', finite=False)
Infinite words over Positive integers
sage: Words('natural numbers')
Finite and infinite words over Non negative integers
```

class sage.combinat.words.words.**Words_n**(*words*, *n*)

Bases: Parent

The set of words of fixed length on a given alphabet.

alphabet()

Return the underlying alphabet.

EXAMPLES:

```
sage: Words([0,1], 4).alphabet()
{0, 1}
```

cardinality()

Returns the number of words of length n from alphabet.

EXAMPLES:

```
sage: Words(['a','b','c'], 4).cardinality()
81
sage: Words(3, 4).cardinality()
81
sage: Words(0,0).cardinality()
1
sage: Words(5,0).cardinality()
1
sage: Words(['a','b','c'],0).cardinality()
1
sage: Words(0,1).cardinality()
0
sage: Words(5,1).cardinality()
5
sage: Words(['a','b','c'],1).cardinality()
3
sage: Words(7,13).cardinality()
96889010407
sage: Words(['a','b','c','d','e','f','g'],13).cardinality()
96889010407
```

iterate_by_length(*length*)

All words in this class are of the same length, so use iterator instead.

list()

Returns a list of all the words contained in self.

EXAMPLES:

```
sage: Words(0,0).list()
[word: ]
sage: Words(5,0).list()
[word: ]
sage: Words(['a','b','c'],0).list()
[word: ]
sage: Words(5,1).list()
[word: 1, word: 2, word: 3, word: 4, word: 5]
sage: Words(['a','b','c'],2).list()
[word: aa, word: ab, word: ac, word: ba, word: bb, word: bc, word: ca, word:␣
↪cb, word: cc]
```

random_element(**args*, ***kwds*)

Return a random word in this set.

EXAMPLES:

```
sage: W = Words('ab', 4)
sage: W.random_element()  # random
word: bbab
sage: W.random_element() in W
True

sage: W = Words(ZZ, 5)
sage: W.random_element()  # random
word: 1,2,2,-1,12
sage: W.random_element() in W
True
```

5.1.372 Yang-Baxter Graphs

class sage.combinat.yang_baxter_graph.**SwapIncreasingOperator**(*i*)

Bases: *SwapOperator*

class sage.combinat.yang_baxter_graph.**SwapOperator**(*i*)

Bases: SageObject

The operator that swaps the items in positions `i` and `i+1`.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapOperator
sage: s3 = SwapOperator(3)
sage: s3 == loads(dumps(s3))
True
```

position()

`self` is the operator that swaps positions `i` and `i+1`. This method returns `i`.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapOperator
sage: s3 = SwapOperator(3)
sage: s3.position()
3
```

sage.combinat.yang_baxter_graph.**YangBaxterGraph**(*partition=None*, *root=None*, *operators=None*)

Construct the Yang-Baxter graph from `root` by repeated application of `operators`, or the Yang-Baxter graph associated to `partition`.

INPUT:

The user needs to provide either `partition` or both `root` and `operators`, where

- `partition` – a partition of a positive integer
- `root` – the root vertex
- `operator` – a function that maps vertices u to a list of tuples of the form (v, l) where v is a successor of u and l is the label of the edge from u to v.

OUTPUT:

- Either:
  - *YangBaxterGraph_partition* – if partition is defined

– *YangBaxterGraph_generic* – if partition is None

EXAMPLES:

The Yang-Baxter graph defined by a partition $[p_1, \ldots, p_k]$ is the labelled directed graph with vertex set obtained by bubble-sorting $(p_k - 1, p_k - 2, \ldots, 0, \ldots, p_1 - 1, p_1 - 2, \ldots, 0)$; there is an arrow from u to v labelled by i if v is obtained by swapping the i-th and $(i+1)$-th elements of u. For example, if the partition is $[3, 1]$, then we begin with $(0, 2, 1, 0)$ and generate all tuples obtained from it by swapping two adjacent entries if they are increasing:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: bubbleswaps = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=bubbleswaps); Y
Yang-Baxter graph with root vertex (0, 2, 1, 0)
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
```

The `partition` keyword is a shorthand for the above construction:

```
sage: Y = YangBaxterGraph(partition=[3,1]); Y                                  #␣
↪needs sage.combinat
Yang-Baxter graph of [3, 1], with top vertex (0, 2, 1, 0)
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
```

The permutahedron can be realized as a Yang-Baxter graph:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: swappers = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(1,2,3,4), operators=swappers); Y
Yang-Baxter graph with root vertex (1, 2, 3, 4)
sage: Y.plot()                                                                 #␣
↪needs sage.plot
Graphics object consisting of 97 graphics primitives
```

The Cayley graph of a finite group can be realized as a Yang-Baxter graph:

```
sage: # needs sage.groups
sage: def left_multiplication_by(g):
....:     return lambda h: h*g
sage: G = CyclicPermutationGroup(4)
sage: operators = [ left_multiplication_by(gen) for gen in G.gens() ]
sage: Y = YangBaxterGraph(root=G.identity(), operators=operators); Y
Yang-Baxter graph with root vertex ()
sage: Y.plot(edge_labels=False)                                                #␣
↪needs sage.plot
Graphics object consisting of 9 graphics primitives

sage: # needs sage.groups
sage: G = SymmetricGroup(4)

AUTHORS:

- Franco Saliola (2009-04-23)

class sage.combinat.yang_baxter_graph.**YangBaxterGraph_generic**(*root*, *operators*)

Bases: SageObject

A class to model the Yang-Baxter graph defined by `root` and `operators`.

INPUT:

- `root` – the root vertex of the graph
- `operators` – a list of callables that map vertices to (new) vertices.

Note: This is a lazy implementation: the digraph is only computed when it is needed.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops); Y
Yang-Baxter graph with root vertex (1, 0, 2, 1, 0)
sage: loads(dumps(Y)) == Y
True
```

AUTHORS:

- Franco Saliola (2009-04-23)

edges()

Return the (labelled) edges of `self`.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: Y.edges()
[((0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0), ((2, 0, 1,␣
↪0), (2, 1, 0, 0), Swap-if-increasing at position 1)]
```

plot(**args*, ***kwds*)

Plot `self` as a digraph.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
sage: Y.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 16 graphics primitives
sage: Y.plot(edge_labels=False)                                             #␣
↪needs sage.plot
Graphics object consisting of 11 graphics primitives
```

relabel_edges(*edge_dict*, *inplace=True*)

Relabel the edges of `self`.

INPUT:

- `edge_dict` – a dictionary keyed by the (unlabelled) edges.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: def relabel_op(op, u):
....:     i = op.position()
....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]
sage: Y.edges()
[((0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0), ((2, 0, 1,␣
↪0), (2, 1, 0, 0), Swap-if-increasing at position 1)]
sage: d = {((0,2,1,0),(2,0,1,0)):17, ((2,0,1,0),(2,1,0,0)):27}
sage: Y.relabel_edges(d, inplace=False).edges()
[((0, 2, 1, 0), (2, 0, 1, 0), 17), ((2, 0, 1, 0), (2, 1, 0, 0), 27)]
sage: Y.edges()
[((0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0), ((2, 0, 1,␣
↪0), (2, 1, 0, 0), Swap-if-increasing at position 1)]
sage: Y.relabel_edges(d, inplace=True)
sage: Y.edges()
[((0, 2, 1, 0), (2, 0, 1, 0), 17), ((2, 0, 1, 0), (2, 1, 0, 0), 27)]
```

relabel_vertices(*v*, *relabel_operator*, *inplace=True*)

Relabel the vertices `u` of `self` by the object obtained from `u` by applying the `relabel_operator` to `v` along a path from `self.root()` to `u`.

Note that the `self.root()` is paired with `v`.

INPUT:

- `v` – tuple, Permutation, …
- `inplace` – if `True`, modifies `self`; otherwise returns a modified copy of `self`.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: def relabel_op(op, u):
....:     i = op.position()
....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]
sage: d = Y.relabel_vertices((1,2,3,4), relabel_op, inplace=False); d
Yang-Baxter graph with root vertex (1, 2, 3, 4)
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
sage: e = Y.relabel_vertices((1,2,3,4), relabel_op); e
sage: Y.vertices(sort=True)
[(1, 2, 3, 4), (2, 1, 3, 4), (2, 3, 1, 4)]
```

root()

Return the root vertex of `self`.

If `self` is the Yang-Baxter graph of the partition $[p_1, p_2, \ldots, p_k]$, then this is the vertex $(p_k - 1, p_k - 2, \ldots, 0, \ldots, p_1 - 1, p_1 - 2, \ldots, 0)$.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
```

(continues on next page)

(continued from previous page)

```
sage: Y.root()
(1, 0, 2, 1, 0)
sage: Y = YangBaxterGraph(root=(0,1,0,2,1,0), operators=ops)
sage: Y.root()
(0, 1, 0, 2, 1, 0)
sage: Y = YangBaxterGraph(root=(1,0,3,2,1,0), operators=ops)
sage: Y.root()
(1, 0, 3, 2, 1, 0)
sage: Y = YangBaxterGraph(partition=[3,2])                                    #␣
↪needs sage.combinat
sage: Y.root()                                                                #␣
↪needs sage.combinat
(1, 0, 2, 1, 0)
```

successors(*v*)

Return the successors of the vertex `v`.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
sage: Y.successors(Y.root())
[(1, 2, 0, 1, 0)]
sage: sorted(Y.successors((1, 2, 0, 1, 0)))
[(1, 2, 1, 0, 0), (2, 1, 0, 1, 0)]
```

vertex_relabelling_dict(*v*, *relabel_operator*)

Return a dictionary pairing vertices `u` of `self` with the object obtained from `v` by applying the `relabel_operator` along a path from the root to `u`.

Note that the root is paired with `v`.

INPUT:

- `v` – an object
- `relabel_operator` – function mapping a vertex and a label to the image of the vertex

OUTPUT:

- dictionary pairing vertices with the corresponding image of `v`

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: def relabel_operator(op, u):
....:     i = op.position()
....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]
sage: Y.vertex_relabelling_dict((1,2,3,4), relabel_operator)
{(0, 2, 1, 0): (1, 2, 3, 4),
 (2, 0, 1, 0): (2, 1, 3, 4),
 (2, 1, 0, 0): (2, 3, 1, 4)}
```

vertices(*sort=False*)

Return the vertices of `self`.

INPUT:

- `sort` – boolean (default `False`) whether to sort the vertices

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
```

class sage.combinat.yang_baxter_graph.**YangBaxterGraph_partition**(*partition*)

Bases: *YangBaxterGraph_generic*

A class to model the Yang-Baxter graph of a partition.

The Yang-Baxter graph defined by a partition $[p_1, \ldots, p_k]$ is the labelled directed graph with vertex set obtained by bubble-sorting $(p_k - 1, p_k - 2, \ldots, 0, \ldots, p_1 - 1, p_1 - 2, \ldots, 0)$; there is an arrow from u to v labelled by i if v is obtained by swapping the i-th and $(i + 1)$-th elements of u.

Note: This is a lazy implementation: the digraph is only computed when it is needed.

EXAMPLES:

```
sage: Y = YangBaxterGraph(partition=[3,2,1]); Y                                 #␣
↪needs sage.combinat
Yang-Baxter graph of [3, 2, 1], with top vertex (0, 1, 0, 2, 1, 0)
sage: loads(dumps(Y)) == Y                                                      #␣
↪needs sage.combinat
True
```

AUTHORS:

- Franco Saliola (2009-04-23)

relabel_vertices(*v*, *inplace=True*)

Relabel the vertices of `self` with the object obtained from `v` by applying the transpositions corresponding to the edge labels along some path from the root to the vertex.

INPUT:

- `v` – tuple, Permutation, …
- `inplace` – if `True`, modifies `self`; otherwise returns a modified copy of `self`.

EXAMPLES:

```
sage: # needs sage.combinat
sage: Y = YangBaxterGraph(partition=[3,1]); Y
Yang-Baxter graph of [3, 1], with top vertex (0, 2, 1, 0)
sage: d = Y.relabel_vertices((1,2,3,4), inplace=False); d
Digraph on 3 vertices
sage: Y.vertices(sort=True)
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
sage: e = Y.relabel_vertices((1,2,3,4)); e
sage: Y.vertices(sort=True)
[(1, 2, 3, 4), (2, 1, 3, 4), (2, 3, 1, 4)]
```

vertex_relabelling_dict(*v*)

Return a dictionary pairing vertices `u` of `self` with the object obtained from `v` by applying transpositions corresponding to the edges labels along a path from the root to `u`.

Note that the root is paired with `v`.

INPUT:

- `v` – an object

OUTPUT:

- dictionary pairing vertices with the corresponding image of `v`

EXAMPLES:

```
sage: Y = YangBaxterGraph(partition=[3,1])                                  #␣
↪needs sage.combinat
sage: Y.vertex_relabelling_dict((1,2,3,4))                                  #␣
↪needs sage.combinat
{(0, 2, 1, 0): (1, 2, 3, 4),
 (2, 0, 1, 0): (2, 1, 3, 4),
 (2, 1, 0, 0): (2, 3, 1, 4)}
sage: Y.vertex_relabelling_dict((4,3,2,1))                                  #␣
↪needs sage.combinat
{(0, 2, 1, 0): (4, 3, 2, 1),
 (2, 0, 1, 0): (3, 4, 2, 1),
 (2, 1, 0, 0): (3, 2, 4, 1)}
```

5.1.373 C-Finite Sequences

C-finite infinite sequences satisfy homogeneous linear recurrences with constant coefficients:

$$a_{n+d} = c_0 a_n + c_1 a_{n+1} + \cdots + c_{d-1} a_{n+d-1}, \quad d > 0.$$

CFiniteSequences are completely defined by their ordinary generating function (o.g.f., which is always a `fraction` of `polynomials` over **Z** or **Q**).

EXAMPLES:

```
sage: fibo = CFiniteSequence(x/(1-x-x^2))        # the Fibonacci sequence
sage: fibo
C-finite sequence, generated by -x/(x^2 + x - 1)
sage: fibo.parent()
The ring of C-Finite sequences in x over Rational Field
sage: fibo.parent().category()
Category of commutative rings
sage: C.<x> = CFiniteSequences(QQ)
sage: fibo.parent() == C
True
sage: C
The ring of C-Finite sequences in x over Rational Field
sage: C(x/(1-x-x^2))
C-finite sequence, generated by -x/(x^2 + x - 1)
sage: C(x/(1-x-x^2)) == fibo
True
sage: var('y')
y
```

(continues on next page)

(continued from previous page)

```
sage: CFiniteSequence(y/(1-y-y^2))
C-finite sequence, generated by -y/(y^2 + y - 1)
sage: CFiniteSequence(y/(1-y-y^2)) == fibo
False
```

Finite subsets of the sequence are accessible via python slices:

```
sage: fibo[137]                 #the 137th term of the Fibonacci sequence
19134702400093278081449423917
sage: fibo[137] == fibonacci(137)
True
sage: fibo[0:12]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
sage: fibo[14:4:-2]
[377, 144, 55, 21, 8]
```

They can be created also from the coefficients and start values of a recurrence:

```
sage: r = C.from_recurrence([1,1],[0,1])
sage: r == fibo
True
```

Given enough values, the o.g.f. of a C-finite sequence can be guessed:

```
sage: r = C.guess([0,1,1,2,3,5,8])
sage: r == fibo
True
```

- [Zei2011]

class sage.rings.cfinite_sequence.**CFiniteSequence**(*parent*, *ogf*)

Bases: FieldElement

Create a C-finite sequence given its ordinary generating function.

INPUT:

- ogf – a rational function, the ordinary generating function (can be an element from the symbolic ring, fraction field or polynomial ring)

OUTPUT:

A CFiniteSequence object

EXAMPLES:

```
sage: CFiniteSequence((2-x)/(1-x-x^2))      # the Lucas sequence
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
sage: CFiniteSequence(x/(1-x)^3)            # triangular numbers
C-finite sequence, generated by -x/(x^3 - 3*x^2 + 3*x - 1)
```

Polynomials are interpreted as finite sequences, or recurrences of degree 0:

```
sage: CFiniteSequence(x^2-4*x^5)
Finite sequence [1, 0, 0, -4], offset = 2
sage: CFiniteSequence(1)
Finite sequence [1], offset = 0
```

This implementation allows any polynomial fraction as o.g.f. by interpreting any power of x dividing the o.g.f. numerator or denominator as a right or left shift of the sequence offset:

```
sage: CFiniteSequence(x^2+3/x)
Finite sequence [3, 0, 0, 1], offset = -1
sage: CFiniteSequence(1/x+4/x^3)
Finite sequence [4, 0, 1], offset = -3
sage: P = LaurentPolynomialRing(QQ.fraction_field(), 'X')
sage: X=P.gen()
sage: CFiniteSequence(1/(1-X))
C-finite sequence, generated by -1/(X - 1)
```

The o.g.f. is always normalized to get a denominator constant coefficient of $+1$:

```
sage: CFiniteSequence(1/(x-2))
C-finite sequence, generated by 1/(x - 2)
```

The given `ogf` is used to create an appropriate parent: it can be a symbolic expression, a polynomial , or a fraction field element as long as it can be coerced into a proper fraction field over the rationals:

```
sage: var('x')
x
sage: f1 = CFiniteSequence((2-x)/(1-x-x^2))
sage: P.<x> = QQ[]
sage: f2 = CFiniteSequence((2-x)/(1-x-x^2))
sage: f1 == f2
True
sage: f1.parent()
The ring of C-Finite sequences in x over Rational Field
sage: f1.ogf().parent()
Fraction Field of Univariate Polynomial Ring in x over Rational Field
sage: CFiniteSequence(log(x))
Traceback (most recent call last):
...
TypeError: unable to convert log(x) to a rational
```

closed_form(*n='n'*)

Return a symbolic expression in `n`, which equals the n-th term of the sequence.

It is a well-known property of C-finite sequences `a_n` that they have a closed form of the type:

$$a_n = \sum_{i=1}^{d} c_i(n) \cdot r_i^n,$$

where `r_i` are the roots of the characteristic equation and `c_i(n)` is a polynomial (whose degree equals the

multiplicity of `r_i` minus one). This is a natural generalization of Binet's formula for Fibonacci numbers. See, for instance, [KP2011, Theorem 4.1].

Note that if the o.g.f. has a polynomial part, that is, if the numerator degree is not strictly less than the denominator degree, then this closed form holds only when `n` exceeds the degree of that polynomial part. In that case, the returned expression will differ from the sequence for small `n`.

EXAMPLES:

```
sage: CFiniteSequence(1/(1-x)).closed_form()
1
sage: CFiniteSequence(x^2/(1-x)).closed_form()
1
sage: CFiniteSequence(1/(1-x^2)).closed_form()
1/2*(-1)^n + 1/2
sage: CFiniteSequence(1/(1+x^3)).closed_form()
1/3*(-1)^n + 1/3*(1/2*I*sqrt(3) + 1/2)^n + 1/3*(-1/2*I*sqrt(3) + 1/2)^n
sage: CFiniteSequence(1/(1-x)/(1-2*x)/(1-3*x)).closed_form()
9/2*3^n - 4*2^n + 1/2
```

Binet's formula for the Fibonacci numbers:

```
sage: CFiniteSequence(x/(1-x-x^2)).closed_form()
sqrt(1/5)*(1/2*sqrt(5) + 1/2)^n - sqrt(1/5)*(-1/2*sqrt(5) + 1/2)^n
sage: [_.subs(n=k).full_simplify() for k in range(6)]
[0, 1, 1, 2, 3, 5]

sage: CFiniteSequence((4*x+3)/(1-2*x-5*x^2)).closed_form()
1/2*(sqrt(6) + 1)^n*(7*sqrt(1/6) + 3) - 1/2*(-sqrt(6) + 1)^n*(7*sqrt(1/6) - 3)
```

Examples with multiple roots:

```
sage: CFiniteSequence(x*(x^2+4*x+1)/(1-x)^5).closed_form()
1/4*n^4 + 1/2*n^3 + 1/4*n^2
sage: CFiniteSequence((1+2*x-x^2)/(1-x)^4/(1+x)^2).closed_form()
1/12*n^3 - 1/8*(-1)^n*(n + 1) + 3/4*n^2 + 43/24*n + 9/8
sage: CFiniteSequence(1/(1-x)^3/(1-2*x)^4).closed_form()
4/3*(n^3 - 3*n^2 + 20*n - 36)*2^n + 1/2*n^2 + 19/2*n + 49
sage: CFiniteSequence((x/(1-x-x^2))^2).closed_form()
1/5*(n - sqrt(1/5))*(1/2*sqrt(5) + 1/2)^n + 1/5*(n + sqrt(1/5))*(-1/2*sqrt(5)␣
↪+ 1/2)^n
```

coefficients()

Return the coefficients of the recurrence representation of the C-finite sequence.

OUTPUT:

- A list of values

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: lucas = C((2-x)/(1-x-x^2))    # the Lucas sequence
sage: lucas.coefficients()
[1, 1]
```

denominator()

Return the numerator of the o.g.f of `self`.

EXAMPLES:

```
sage: f = CFiniteSequence((2-x)/(1-x-x^2)); f
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
sage: f.denominator()
x^2 + x - 1
```

numerator()

Return the numerator of the o.g.f of `self`.

EXAMPLES:

```
sage: f = CFiniteSequence((2-x)/(1-x-x^2)); f
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
sage: f.numerator()
x - 2
```

ogf()

Return the ordinary generating function associated with the CFiniteSequence.

This is always a fraction of polynomials in the base ring.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: r = C.from_recurrence([2],[1])
sage: r.ogf()
-1/2/(x - 1/2)
sage: C(0).ogf()
0
```

recurrence_repr()

Return a string with the recurrence representation of the C-finite sequence.

OUTPUT:

A string

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C((2-x)/(1-x-x^2)).recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 2: a(n+2)␣
↪= a(n+1) + a(n), starting a(0...) = [2, 1]'
sage: C(x/(1-x)^3).recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 3: a(n+3)␣
↪= 3*a(n+2) - 3*a(n+1) + a(n), starting a(1...) = [1, 3, 6]'
sage: C(1).recurrence_repr()
'Finite sequence [1], offset 0'
sage: r = C((-2*x^3 + x^2 - x + 1)/(2*x^2 - 3*x + 1))
sage: r.recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 2: a(n+2)␣
↪= 3*a(n+1) - 2*a(n), starting a(0...) = [1, 2, 5, 9]'
sage: r = CFiniteSequence(x^3/(1-x-x^2))
sage: r.recurrence_repr()
'homogeneous linear recurrence with constant coefficients of degree 2: a(n+2)␣
↪= a(n+1) + a(n), starting a(3...) = [1, 1, 2, 3]'
```

series(n)

Return the Laurent power series associated with the CFiniteSequence, with precision n.

INPUT:

- n – a nonnegative integer

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: r = C.from_recurrence([-1,2],[0,1])
sage: s = r.series(4); s
x + 2*x^2 + 3*x^3 + 4*x^4 + O(x^5)
sage: type(s)
<class 'sage.rings.laurent_series_ring_element.LaurentSeries'>
```

sage.rings.cfinite_sequence.**CFiniteSequences**(*base_ring*, *names=None*, *category=None*)

Return the commutative ring of C-Finite sequences.

The ring is defined over a base ring (**Z** or **Q**) and each element is represented by its ordinary generating function (ogf) which is a rational function over the base ring.

INPUT:

- `base_ring` – the base ring to construct the fraction field representing the C-Finite sequences
- `names` – (optional) the list of variables.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C
The ring of C-Finite sequences in x over Rational Field
sage: C.an_element()
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
sage: C.category()
Category of commutative rings
sage: C.one()
Finite sequence [1], offset = 0
sage: C.zero()
Constant infinite sequence 0.
sage: C(x)
Finite sequence [1], offset = 1
sage: C(1/x)
Finite sequence [1], offset = -1
sage: C((-x + 2)/(-x^2 - x + 1))
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
```

class sage.rings.cfinite_sequence.**CFiniteSequences_generic**(*polynomial_ring*, *category*)

Bases: `Parent`, `UniqueRepresentation`

The class representing the ring of C-Finite Sequences

Element

alias of *CFiniteSequence*

an_element()

Return an element of C-Finite Sequences.

OUTPUT:

The Lucas sequence.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.an_element()
C-finite sequence, generated by (x - 2)/(x^2 + x - 1)
```

fraction_field()

Return the fraction field used to represent the elements of `self`.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.fraction_field()
Fraction Field of Univariate Polynomial Ring in x over Rational Field
```

from_recurrence(*coefficients*, *values*)

Create a C-finite sequence given the coefficients c and starting values a of a homogeneous linear recurrence.

$$a_{n+d} = c_0 a_n + c_1 a_{n+1} + \cdots + c_{d-1} a_{n+d-1}, \quad d \geq 0.$$

INPUT:

- `coefficients` – a list of rationals
- `values` – start values, a list of rationals

OUTPUT:

- A CFiniteSequence object

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.from_recurrence([1,1],[0,1])    # Fibonacci numbers
C-finite sequence, generated by -x/(x^2 + x - 1)
sage: C.from_recurrence([-1,2],[0,1])     # natural numbers
C-finite sequence, generated by x/(x^2 - 2*x + 1)
sage: r = C.from_recurrence([-1],[1])
sage: s = C.from_recurrence([-1],[1,-1])
sage: r == s
True
sage: r = C(x^3/(1-x-x^2))
sage: s = C.from_recurrence([1,1],[0,0,0,1,1])
sage: r == s
True
sage: C.from_recurrence(1,1)
Traceback (most recent call last):
...
ValueError: Wrong type for recurrence coefficient list.
```

gen(*i=0*)

Return the i-th generator of `self`.

INPUT:

- `i` – an integer (default:0)

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.gen()
```

(continues on next page)

(continued from previous page)

```
x
sage: x == C.gen()
True
```

gens()

Return the generators of `self`.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.gens()
(x,)
```

guess(*sequence*, *algorithm='sage'*)

Return the minimal CFiniteSequence that generates the sequence.

Assume the first value has index 0.

INPUT:

- `sequence` – list of integers
- **`algorithm` – string**
  - 'sage' – the default is to use Sage's matrix kernel function
  - 'pari' – use Pari's implementation of LLL
  - 'bm' – use Sage's Berlekamp-Massey algorithm

OUTPUT:

- a CFiniteSequence, or 0 if none could be found

With the default kernel method, trailing zeroes are chopped off before a guessing attempt. This may reduce the data below the accepted length of six values.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.guess([1,2,4,8,16,32])
C-finite sequence, generated by -1/2/(x - 1/2)
sage: r = C.guess([1,2,3,4,5])
Traceback (most recent call last):
...
ValueError: sequence too short for guessing
```

With Berlekamp-Massey, if an odd number of values is given, the last one is dropped. So with an odd number of values the result may not generate the last value:

```
sage: r = C.guess([1,2,4,8,9], algorithm='bm'); r
C-finite sequence, generated by -1/2/(x - 1/2)
sage: r[0:5]
[1, 2, 4, 8, 16]
```

ngens()

Return the number of generators of `self`.

EXAMPLES:

```
sage: from sage.rings.cfinite_sequence import CFiniteSequences
sage: C.<x> = CFiniteSequences(QQ)
sage: C.ngens()
1
```

polynomial_ring()

Return the polynomial ring used to represent the elements of `self`.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.polynomial_ring()
Univariate Polynomial Ring in x over Rational Field
```
